[NumPy](#), [Image](#), [Audio](#), [Games](#), [Data](#).

## Main

```
if __name__ == '__main__':    # Runs main() if file wasn't imported.
    main()
```

## List

```
<list> = <list>[<slice>]      # Or: <list>[from_inclusive : to_exclusive :
±step]
```

```
<list>.append(<el>)           # Or: <list> += [<el>]
<list>.extend(<collection>)    # Or: <list> += <collection>
```

```
<list>.sort()                 # Sorts in ascending order.
<list>.reverse()              # Reverses the list in-place.
<list> = sorted(<collection>)  # Returns a new sorted list.
<iter> = reversed(<list>)     # Returns reversed iterator.
```

```
sum_of_elements   = sum(<collection>)
elementwise_sum   = [sum(pair) for pair in zip(list_a, list_b)]
sorted_by_second  = sorted(<collection>, key=lambda el: el[1])
sorted_by_both    = sorted(<collection>, key=lambda el: (el[1], el[0]))
flatter_list      = list(itertools.chain.from_iterable(<list>))
product_of_elems  = functools.reduce(lambda out, el: out * el, <collection>)
list_of_chars     = list(<str>)
```

- For details about `sorted()`, `min()` and `max()` see [sortable](#).
- Module [operator](#) provides functions `itemgetter()` and `mul()` that offer the same functionality as [lambda](#) expressions above.

```
<list>.insert(<int>, <el>)      # Inserts item at index and moves the rest to the
right.
<el> = <list>.pop([<int>])      # Removes and returns item at index or from the
end.
<int> = <list>.count(<el>)      # Returns number of occurrences. Also works on
strings.
<int> = <list>.index(<el>)      # Returns index of the first occurrence or raises
ValueError.
<list>.remove(<el>)           # Removes first occurrence of the item or raises
ValueError.
<list>.clear()                # Removes all items. Also works on dictionary and
set.
```

## Dictionary

```
<view> = <dict>.keys()          # Coll. of keys that reflects
changes.
<view> = <dict>.values()        # Coll. of values that reflects
changes.
<view> = <dict>.items()         # Coll. of key-value tuples that
reflects chgs.
```

```
value = <dict>.get(key, default=None) # Returns default if key is
missing.
value = <dict>.setdefault(key, default=None) # Returns and writes default if
key is missing.
<dict> = collections.defaultdict(<type>) # Creates a dict with default
value of type.
<dict> = collections.defaultdict(lambda: 1) # Creates a dict with default
value 1.
```

```
<dict> = dict(<collection>)      # Creates a dict from coll. of
key-value pairs.
<dict> = dict(zip(keys, values)) # Creates a dict from two
collections.
<dict> = dict.fromkeys(keys [, value]) # Creates a dict from collection
of keys.
```

```
<dict>.update(<dict>)            # Adds items. Replaces ones with
matching keys.
value = <dict>.pop(key)          # Removes item or raises
KeyError.
{k for k, v in <dict>.items() if v == value} # Returns set of keys that point
to the value.
{k: v for k, v in <dict>.items() if k in keys} # Returns a dictionary, filtered
by keys.
```

## Counter

```
>>> from collections import Counter
>>> colors = ['blue', 'blue', 'blue', 'red', 'red']
>>> counter = Counter(colors)
>>> counter['yellow'] += 1
Counter({'blue': 3, 'red': 2, 'yellow': 1})
>>> counter.most_common()[0]
('blue', 3)
```

## Set

```
<set> = set()
```

```
<set>.add(<el>) # Or: <set> |= {<el>}
<set>.update(<collection> [, ...]) # Or: <set> |= <set>
```

```
<set> = <set>.union(<coll.>) # Or: <set> | <set>
<set> = <set>.intersection(<coll.>) # Or: <set> & <set>
<set> = <set>.difference(<coll.>) # Or: <set> - <set>
<set> = <set>.symmetric_difference(<coll.>) # Or: <set> ^ <set>
<bool> = <set>.issubset(<coll.>) # Or: <set> <= <set>
<bool> = <set>.issuperset(<coll.>) # Or: <set> >= <set>
```

```
<el> = <set>.pop() # Raises KeyError if empty.
<set>.remove(<el>) # Raises KeyError if missing.
<set>.discard(<el>) # Doesn't raise an error.
```

## Frozen Set

- Is immutable and hashable.
- That means it can be used as a key in a dictionary or as an element in a set.

```
<frozenset> = frozenset(<collection>)
```

## Tuple

Tuple is an immutable and hashable list.

```
<tuple> = ()
<tuple> = (<el>,) # Or: <el>,
<tuple> = (<el_1>, <el_2> [, ...]) # Or: <el_1>, <el_2> [, ...]
```

## Named Tuple

Tuple's subclass with named elements.

```
>>> from collections import namedtuple
>>> Point = namedtuple('Point', 'x y')
>>> p = Point(1, y=2)
Point(x=1, y=2)
>>> p[0]
1
>>> p.x
1
>>> getattr(p, 'y')
2
>>> p._fields # Or: Point._fields
('x', 'y')
```

## Range

```
<range> = range(to_exclusive)
<range> = range(from_inclusive, to_exclusive)
<range> = range(from_inclusive, to_exclusive, ±step_size)
```

```
from_inclusive = <range>.start
to_exclusive   = <range>.stop
```

## Enumerate

```
for i, el in enumerate(<collection> [, i_start]):
    ...
```

## Iterator

```
<iter> = iter(<collection>)                # `iter(<iter>)` returns unmodified
iter.
<iter> = iter(<function>, to_exclusive)     # A sequence of return values until
'to_exclusive'.
<el>   = next(<iter> [, default])           # Raises StopIteration or returns
'default' on end.
<list> = list(<iter>)                       # Returns a list of iterator's
remaining elements.
```

## Itertools

```
from itertools import count, repeat, cycle, chain, islice
```

```
<iter> = count(start=0, step=1)             # Returns updated value endlessly.
Accepts floats.
<iter> = repeat(<el> [, times])             # Returns element endlessly or
'times' times.
<iter> = cycle(<collection>)                # Repeats the sequence endlessly.
```

```
<iter> = chain(<coll_1>, <coll_2> [, ...]) # Empties collections in order
(figuratively).
<iter> = chain.from_iterable(<collection>) # Empties collections inside a
collection in order.
```

```
<iter> = islice(<coll>, to_exclusive) # Only returns first 'to_exclusive'
elements.
<iter> = islice(<coll>, from_inclusive, ...) # `to_exclusive, step_size`.
```

## Generator

- Any function that contains a yield statement returns a generator.
- Generators and iterators are interchangeable.

```
def count(start, step):
    while True:
        yield start
        start += step
```

```
>>> counter = count(10, 2)
>>> next(counter), next(counter), next(counter)
(10, 12, 14)
```

## Type

- Everything is an object.
- Every object has a type.
- Type and class are synonymous.

```
<type> = type(<el>) # Or: <el>.__class__
<bool> = isinstance(<el>, <type>) # Or: isinstance(type(<el>),
<type>)
```

```
>>> type('a'), 'a'.__class__, str
(<class 'str'>, <class 'str'>, <class 'str'>)
```

**Some types do not have built-in names, so they must be imported:**

```
from types import FunctionType, MethodType, LambdaType, GeneratorType,
ModuleType
```

## Abstract Base Classes

Each abstract base class specifies a set of virtual subclasses. These classes are then recognized by `isinstance()` and `issubclass()` as subclasses of the ABC, although they are really not. ABC can also manually decide whether or not a specific class is its virtual subclass, usually based on which methods the class has implemented. For instance, Iterable ABC looks for method `iter()`, while Collection ABC looks for `iter()`, `contains()` and `len()`.

```
>>> from collections.abc import Iterable, Collection, Sequence
>>> isinstance([1, 2, 3], Iterable)
True
```

	Iterable	Collection	Sequence
list, range, str	yes	yes	yes
dict, set	yes	yes	
iter	yes		

```
>>> from numbers import Number, Complex, Real, Rational, Integral
>>> isinstance(123, Number)
True
```

	Number	Complex	Real	Rational	Integral
int	yes	yes	yes	yes	yes
fractions.Fraction	yes	yes	yes	yes	
float	yes	yes	yes		
complex	yes	yes			
decimal.Decimal	yes				

## String

```
<str> = <str>.strip() # Strips all whitespace characters
from both ends.
<str> = <str>.strip('<chars>') # Strips all passed characters from
both ends.
```

```
<list> = <str>.split() # Splits on one or more whitespace
characters.
<list> = <str>.split(sep=None, maxsplit=-1) # Splits on 'sep' str at most
'maxsplit' times.
<list> = <str>.splitlines(keepends=False) # On [\n\r\f\v\x1c-
\x1e\x85\u2028\u2029] and \r\n.
<str> = <str>.join(<coll_of_strings>) # Joins elements using string as a
separator.
```

```

<bool> = <sub_str> in <str>                # Checks if string contains a
substring.
<bool> = <str>.startswith(<sub_str>)        # Pass tuple of strings for
multiple options.
<bool> = <str>.endswith(<sub_str>)          # Pass tuple of strings for
multiple options.
<int>  = <str>.find(<sub_str>)              # Returns start index of the first
match or -1.
<int>  = <str>.index(<sub_str>)             # Same, but raises ValueError if
missing.

```

```

<str>  = <str>.replace(old, new [, count])  # Replaces 'old' with 'new' at most
'count' times.
<str>  = <str>.translate(<table>)          # Use `str.maketrans(<dict>)` to
generate table.

```

```

<str>  = chr(<int>)                        # Converts int to Unicode
character.
<int>  = ord(<str>)                        # Converts Unicode character to
int.

```

- Also: 'lstrip()', 'rstrip()' and 'rsplit()'.
- Also: 'lower()', 'upper()', 'capitalize()' and 'title()'.

## Property Methods

	[ !#\$%...]	[a-zA-Z]	[%/2%]	[ <sup>2</sup> ³¹]	[0-9]	
isprintable()	yes	yes	yes	yes	yes	
isalnum()		yes	yes	yes	yes	
isnumeric()			yes	yes	yes	
isdigit()				yes	yes	
isdecimal()					yes	

- Also: 'isspace()' checks for '[ \t\n\r\f\v\x1c-\x1f\x85...]'

## Regex

```

import re
<str>  = re.sub(<regex>, new, text, count=0) # Substitutes all occurrences
with 'new'.
<list> = re.findall(<regex>, text)           # Returns all occurrences as
strings.
<list> = re.split(<regex>, text, maxsplit=0) # Use brackets in regex to
include the matches.
<Match> = re.search(<regex>, text)           # Searches for first occurrence
of the pattern.
<Match> = re.match(<regex>, text)            # Searches only at the beginning
of the text.
<iter> = re.finditer(<regex>, text)          # Returns all occurrences as
Match objects.

```

- Argument 'new' can be a function that accepts a Match object and returns a string.
- Search() and match() return None if they can't find a match.
- Argument 'flags=re.IGNORECASE' can be used with all functions.
- Argument 'flags=re.MULTILINE' makes '^' and '\$' match the start/end of each line.
- Argument 'flags=re.DOTALL' makes dot also accept the '\n'.
- Use 'r'\1' or '\\1' for backreference ('\\1' returns a character with octal code 1).
- Add '?' after '\*' and '+' to make them non-greedy.

## Match Object

```

<str>  = <Match>.group()                    # Returns the whole match. Also
group(0).
<str>  = <Match>.group(1)                    # Returns part in the first
bracket.
<tuple> = <Match>.groups()                  # Returns all bracketed parts.
<int>   = <Match>.start()                   # Returns start index of the
match.
<int>   = <Match>.end()                     # Returns exclusive end index of
the match.

```

## Special Sequences

```

'\d' == '[0-9]'          # Matches decimal characters.
'\w' == '[a-zA-Z0-9_]'   # Matches alphanumerics and
underscore.
'\s' == '[\t\n\r\f\v]'  # Matches whitespaces.

```

- By default, decimal characters, alphanumerics and whitespaces from all alphabets are matched unless 'flags=re.ASCII' argument is used.
- As shown above, it restricts all special sequence matches to the first 128 characters and prevents '\s' from accepting '[\x1c-\x1f]' (the so-called separator characters).
- Use a capital letter for negation (all non-ASCII characters will be matched when used in combination with ASCII flag).

## Format

```
<str> = f'{{<el_1>}}, {{<el_2>}}'           # Or: '{{}}, {{}}'.format(<el_1>, <el_2>)
<str> = '%s, %s' % (<el_1>, <el_2>)         # Redundant and inferior C style
formatting.
```

## Attributes

```
>>> from collections import namedtuple
>>> Person = namedtuple('Person', 'name height')
>>> person = Person('Jean-Luc', 187)
>>> f'{person.height}'
'187'
>>> '{p.height}'.format(p=person)
'187'
```

## General Options

```
{{el>:<10}}           # 'el>      '
{{el>:^10}}            # '      el>  '
{{el>:>10}}             # '        el>'
{{el>:..<10}}          # 'el>.....'
{{el>:0}}               # 'el>'
```

- Options can be generated dynamically: `f'{{el>:{{str/int}}[...]]}'`.
- Adding `'!r'` before the colon converts object to string by calling its [repr\(\)](#) method.

## Strings

```
{{'abcde':10}}        # 'abcde      '
{{'abcde':10.3}}       # 'abc        '
{{'abcde':.3}}         # 'abc'
{{'abcde'!r:10}}       # "'abcde'    "
```

## Numbers

```
{{123456:10}}         # '      123456'
{{123456:10,}}         # '      123,456'
{{123456:10_}}         # '      123_456'
{{123456:+10}}         # '      +123456'
{{123456:+=10}}        # '      + 123456'
{{123456: }}           # '      123456'
{{-123456: }}          # '     -123456'
```

## Floats

```
{{1.23456:10.3}}      # '          1.23'
{{1.23456:10.3f}}      # '          1.235'
{{1.23456:10.3e}}      # '      1.235e+00'
{{1.23456:10.3%}}      # '      123.456%'
```

## Comparison of presentation types:

```
+-----+-----+-----+-----+-----+

|
+-----+-----+-----+-----+-----+
--+
```

- When both rounding up and rounding down are possible, the one that returns result with even last digit is chosen. That makes `'{6.5:.0f}'` a `'6'` and `'{7.5:.0f}'` an `'8'`.
- This rule only effects numbers that can be represented exactly by a float (`.5`, `.25`, ...).

## Ints

```
{90:c}          # 'Z'
{90:b}          # '1011010'
{90:x}          # '5A'
```

## Numbers

```
<int>      = int(<float/str/bool>)      # Or: math.floor(<float>)
<float>    = float(<int/str/bool>)      # Or: <real>e±<int>
<complex>  = complex(real=0, imag=0)    # Or: <real> ± <real>j
<Fraction> = fractions.Fraction(0, 1)    # Or: Fraction(numerator=0,
denominator=1)
<Decimal>  = decimal.Decimal(<str/int>) # Or: Decimal((sign, digits, exponent))
```

- `'int(<str>)'` and `'float(<str>)'` raise **ValueError** on malformed strings.
- Decimal numbers are stored exactly, unlike most floats where `'1.1 + 2.2 != 3.3'`.
- Floats can be compared with: `'math.isclose(<float>, <float>)'`.
- Precision of decimal operations is set with: `'decimal.getcontext().prec = <int>'`.

## Basic Functions

```
<num> = pow(<num>, <num>)      # Or: <num> ** <num>
<num> = abs(<num>)             # <float> = abs(<complex>)
<num> = round(<num> [, ±ndigits]) # `round(126, -1) == 130`
```

## Math

```
from math import e, pi, inf, nan, isinf, isnan
from math import sin, cos, tan, asin, acos, atan, degrees, radians
from math import log, log10, log2
```

## Statistics

```
from statistics import mean, median, variance, stdev, quantiles, groupby
```

## Random

```
from random import random, randint, choice, shuffle, gauss, seed

<float> = random()          # A float inside [0, 1).
<int>   = randint(from_inc, to_inc) # An int inside [from_inc, to_inc].
<el>    = choice(<sequence>)      # Keeps the sequence intact.
```

## Bin, Hex

```
<int> = ±0b<bin>                                # Or: ±0x<hex>
<int> = int('±<bin>', 2)                          # Or: int('±<hex>', 16)
<int> = int('±0b<bin>', 0)                        # Or: int('±0x<hex>', 0)
<str> = bin(<int>)                                # Returns '[-]0b<bin>'.
```

## Bitwise Operators

```
<int> = <int> & <int>                             # And (0b1100 & 0b1010 == 0b1000).
<int> = <int> | <int>                             # Or  (0b1100 | 0b1010 == 0b1110).
<int> = <int> ^ <int>                             # Xor (0b1100 ^ 0b1010 == 0b0110).
<int> = <int> << n_bits                          # Left shift. Use >> for right.
<int> = ~<int>                                   # Not. Also -<int> - 1.
```

## Combinatorics

- Every function returns an iterator.
- If you want to print the iterator, you need to pass it to the list() function first!

```
from itertools import product, combinations, combinations_with_replacement,
permutations
```

```
>>> product([0, 1], repeat=3)
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (0, 1, 1), ..., (1, 1, 1)]
```

```
>>> product('abc', 'abc')                        #   a   b   c
[('a', 'a'), ('a', 'b'), ('a', 'c'),           # a x   x   x
 ('b', 'a'), ('b', 'b'), ('b', 'c'),           # b x   x   x
 ('c', 'a'), ('c', 'b'), ('c', 'c')]           # c x   x   x
```

```
>>> combinations('abc', 2)                       #   a   b   c
[('a', 'b'), ('a', 'c'),                       # a .   x   x
 ('b', 'c')]                                   # b .   .   x
```

```
>>> combinations_with_replacement('abc', 2)      #   a   b   c
[('a', 'a'), ('a', 'b'), ('a', 'c'),           # a x   x   x
 ('b', 'b'), ('b', 'c'),                       # b .   x   x
 ('c', 'c')]                                   # c .   .   x
```

```
>>> permutations('abc', 2)                      #   a   b   c
[('a', 'b'), ('a', 'c'),                       # a .   x   x
 ('b', 'a'), ('b', 'c'),                       # b x   .   x
 ('c', 'a'), ('c', 'b')]                       # c x   x   .
```

## Datetime

- Module 'datetime' provides 'date' <D>, 'time' <T>, 'datetime' <DT> and 'timedelta' <TD> classes. All are immutable and hashable.

- Time and datetime objects can be 'aware' `<a>`, meaning they have defined timezone, or 'naive' `<n>`, meaning they don't.
- If object is naive, it is presumed to be in the system's timezone.

```
from datetime import date, time, datetime, timedelta
from dateutil.tz import UTC, tzlocal, gettz, datetime_exists, resolve_imaginary
```

## Constructors

```
<D> = date(year, month, day)
<T> = time(hour=0, minute=0, second=0, microsecond=0, tzinfo=None, fold=0)
<DT> = datetime(year, month, day, hour=0, minute=0, second=0, ...)
<TD> = timedelta(weeks=0, days=0, hours=0, minutes=0, seconds=0, ...)
```

- Use `'<D/DT>.weekday()'` to get the day of the week as an int, with Monday being 0.
- `'fold=1'` means the second pass in case of time jumping back for one hour.
- Timedelta normalizes arguments to  $\pm$ days, seconds ( $< 86400$ ) and microseconds ( $< 1M$ ).

## Now

```
<D/DTn> = D/DT.today() # Current local date or naive datetime.
<DTn>    = DT.utcnow()  # Naive datetime from current UTC time.
<DTa>    = DT.now(<tzinfo>) # Aware datetime from current tz time.
```

- To extract time use `'<DTn>.time()'`, `'<DTa>.time()'` or `'<DTa>.timetz()'`.

## Timezone

```
<tzinfo> = UTC # UTC timezone. London without DST.
<tzinfo> = tzlocal() # Local timezone. Also gettz().
<tzinfo> = gettz('<Continent>/<City>') # 'Continent/City_Name' timezone or None.
<DTa>    = <DT>.astimezone(<tzinfo>) # Datetime, converted to the passed timezone.
<Ta/DTa> = <T/DT>.replace(tzinfo=<tzinfo>) # Unconverted object with a new timezone.
```

## Encode

```

<D/T/DT> = D/T/DT.fromisoformat('<iso>')    # Object from ISO string. Raises
ValueError.
<DT>      = DT.strptime(<str>, '<format>')    # Datetime from str, according to
format.
<D/DTn>   = D/DT.fromordinal(<int>)          # D/DTn from days since the
Gregorian NYE 1.
<DTn>     = DT.fromtimestamp(<real>)          # Local time DTn from seconds since
the Epoch.
<DTa>     = DT.fromtimestamp(<real>, <tz.>)   # Aware datetime from seconds since
the Epoch.

```

- ISO strings come in following forms: 'YYYY-MM-DD', 'HH:MM:SS.mmmuuu[±HH:MM]', or both separated by an arbitrary character. All parts following hours are optional.
- Python uses the Unix Epoch: '1970-01-01 00:00 UTC', '1970-01-01 01:00 CET', ...

## Decode

```

<str>      = <D/T/DT>.isoformat(sep='T')      # Also
timespec='auto/hours/minutes/seconds/...'.
<str>      = <D/T/DT>.strftime('<format>')    # Custom string representation.
<int>      = <D/DT>.toordinal()               # Days since Gregorian NYE 1,
ignoring time and tz.
<float>    = <DTn>.timestamp()                 # Seconds since the Epoch, from DTn
in local tz.
<float>    = <DTa>.timestamp()                 # Seconds since the Epoch, from
aware datetime.

```

## Format

```

>>> dt = datetime.strptime('2015-05-14 23:39:00.00 +2000', '%Y-%m-%d %H:%M:%S.%f
%Z')
>>> dt.strftime("%A, %dth of %B '%y, %I:%M%p %Z")
"Thursday, 14th of May '15, 11:39PM UTC+02:00"

```

- '%Z' only accepts 'UTC/GMT' and local timezone's code. '%Z' also accepts '±HH:MM'.
- For abbreviated weekday and month use '%a' and '%b'.

## Arithmetics

```

<D/DT>     = <D/DT> ± <TD>                    # Returned datetime can fall into
missing hour.
<TD>       = <D/DTn> - <D/DTn>                 # Returns the difference, ignoring
time jumps.
<TD>       = <DTa> - <DTa>                     # Ignores time jumps if they share
tzinfo object.
<TD>       = <TD> * <real>                     # Also: <TD> = abs(<TD>) and <TD> =
<TD> ±% <TD>.
<float>    = <TD> / <TD>                       # How many weeks/years there are in
TD. Also //.

```

## Arguments

## Inside Function Call

```
<function>(<positional_args>)           # f(0, 0)
<function>(<keyword_args>)               # f(x=0, y=0)
<function>(<positional_args>, <keyword_args>) # f(0, y=0)
```

## Inside Function Definition

```
def f(<nondefault_args>):                # def f(x, y):
def f(<default_args>):                   # def f(x=0, y=0):
def f(<nondefault_args>, <default_args>): # def f(x, y=0):
```

- A function has its default values evaluated when it's first encountered in the scope.
- Any changes to default values that are mutable will persist between invocations.

## Splat Operator

### Inside Function Call

Splat expands a collection into positional arguments, while splatty-splat expands a dictionary into keyword arguments.

```
args    = (1, 2)
kwargs  = {'x': 3, 'y': 4, 'z': 5}
func(*args, **kwargs)
```

Is the same as:

```
func(1, 2, x=3, y=4, z=5)
```

### Inside Function Definition

Splat combines zero or more positional arguments into a tuple, while splatty-splat combines zero or more keyword arguments into a dictionary.

```
def add(*a):
    return sum(a)
```

```
>>> add(1, 2, 3)
6
```

Legal argument combinations:

```
def f(*, x, y, z):          # f(x=1, y=2, z=3)
def f(x, *, y, z):          # f(x=1, y=2, z=3) | f(1, y=2, z=3)
def f(x, y, *, z):          # f(x=1, y=2, z=3) | f(1, y=2, z=3) | f(1, 2, z=3)
```

```
def f(*args):           # f(1, 2, 3)
def f(x, *args):       # f(1, 2, 3)
def f(*args, z):       # f(1, 2, z=3)
```

```
def f(**kwargs):       # f(x=1, y=2, z=3)
def f(x, **kwargs):    # f(x=1, y=2, z=3) | f(1, y=2, z=3)
def f(*, x, **kwargs): # f(x=1, y=2, z=3)
```

```
def f(*args, **kwargs): # f(x=1, y=2, z=3) | f(1, y=2, z=3) | f(1, 2, z=3) |
f(1, 2, 3)
def f(x, *args, **kwargs): # f(x=1, y=2, z=3) | f(1, y=2, z=3) | f(1, 2, z=3) |
f(1, 2, 3)
def f(*args, y, **kwargs): # f(x=1, y=2, z=3) | f(1, y=2, z=3)
```

## Other Uses

```
<list>  = [*<collection> [, ...]]
<set>    = {*<collection> [, ...]}
<tuple> = (*<collection>, [...])
<dict>   = {**<dict> [, ...]}
```

```
head, *body, tail = <collection>
```

## Inline

## Lambda

```
<func> = lambda: <return_value>
<func> = lambda <arg_1>, <arg_2>: <return_value>
```

## Comprehensions

```
<list> = [i+1 for i in range(10)]           # [1, 2, ..., 10]
<set>   = {i for i in range(10) if i > 5}    # {6, 7, 8, 9}
<iter>  = (i+5 for i in range(10))          # (5, 6, ..., 14)
<dict>  = {i: i*2 for i in range(10)}        # {0: 0, 1: 2, ..., 9:
18}
```

```
>>> [l+r for l in 'abc' for r in 'abc']
['aa', 'ab', 'ac', ..., 'cc']
```

## Map, Filter, Reduce

```
<iter> = map(lambda x: x + 1, range(10))    # (1, 2, ..., 10)
<iter> = filter(lambda x: x > 5, range(10)) # (6, 7, 8, 9)
<obj>  = reduce(lambda out, x: out + x, range(10)) # 45
```

- Reduce must be imported from the functools module.

## Any, All

```
<bool> = any(<collection>)           # Is `bool(e1)` True
for any element.
<bool> = all(<collection>)           # Is True for all
elements or empty.
```

## Conditional Expression

```
<obj> = <exp_if_true> if <condition> else <exp_if_false>
```

```
>>> [a if a else 'zero' for a in (0, 1, 2, 3)]
['zero', 1, 2, 3]
```

## Named Tuple, Enum, Dataclass

```
from collections import namedtuple
Point = namedtuple('Point', 'x y')
point = Point(0, 0)
```

```
from enum import Enum
Direction = Enum('Direction', 'n e s w')
direction = Direction.n
```

```
from dataclasses import make_dataclass
Creature = make_dataclass('Creature', ['loc', 'dir'])
creature = Creature(point, direction)
```

## Imports

```
import <module>           # Imports a built-in or '<module>.py'.
import <package>          # Imports a built-in or '<package>/__init__.py'.
import <package>.<module> # Imports a built-in or '<package>/<module>.py'.
```

- Package is a collection of modules, but it can also define its own objects.
- On a filesystem this corresponds to a directory of Python files with an optional init script.
- Running `'import <package>'` does not automatically provide access to the package's modules unless they are explicitly imported in its init script.

## Closure

We have/get a closure in Python when:

- A nested function references a value of its enclosing function and then
- the enclosing function returns the nested function.

```
def get_multiplier(a):
    def out(b):
        return a * b
    return out
```

```
>>> multiply_by_3 = get_multiplier(3)
>>> multiply_by_3(10)
30
```

- If multiple nested functions within enclosing function reference the same value, that value gets shared.
- To dynamically access function's first free variable use `'<function>.__closure__[0].cell_contents'`.

## Partial

```
from functools import partial
<function> = partial(<function> [, <arg_1>, <arg_2>, ...])
```

```
>>> import operator as op
>>> multiply_by_3 = partial(op.mul, 3)
>>> multiply_by_3(10)
30
```

- Partial is also useful in cases when function needs to be passed as an argument because it enables us to set its arguments beforehand.
- A few examples being: `'defaultdict(<function>)', 'iter(<function>, to_exclusive)'` and `dataclass's 'field(default_factory=<function>'`.

## Non-Local

If variable is being assigned to anywhere in the scope, it is regarded as a local variable, unless it is declared as a 'global' or a 'nonlocal'.

```
def get_counter():
    i = 0
    def out():
        nonlocal i
        i += 1
        return i
    return out
```

```
>>> counter = get_counter()
>>> counter(), counter(), counter()
(1, 2, 3)
```

## Decorator

- A decorator takes a function, adds some functionality and returns it.
- It can be any [callable](#), but is usually implemented as a function that returns a [closure](#).

```
@decorator_name
def function_that_gets_passed_to_decorator():
    ...
```

## Debugger Example

Decorator that prints function's name every time the function is called.

```
from functools import wraps

def debug(func):
    @wraps(func)
    def out(*args, **kwargs):
        print(func.__name__)
        return func(*args, **kwargs)
    return out

@debug
def add(x, y):
    return x + y
```

- Wraps is a helper decorator that copies the metadata of the passed function (func) to the function it is wrapping (out).
- Without it `'add.__name__'` would return `'out'`.

## LRU Cache

Decorator that caches function's return values. All function's arguments must be hashable.

```
from functools import lru_cache

@lru_cache(maxsize=None)
def fib(n):
    return n if n < 2 else fib(n-2) + fib(n-1)
```

- Default size of the cache is 128 values. Passing `'maxsize=None'` makes it unbounded.
- CPython interpreter limits recursion depth to 1000 by default. To increase it use `'sys.setrecursionlimit(<depth>)'`.

## Parametrized Decorator

A decorator that accepts arguments and returns a normal decorator that accepts a function.

```
from functools import wraps

def debug(print_result=False):
    def decorator(func):
        @wraps(func)
        def out(*args, **kwargs):
            result = func(*args, **kwargs)
            print(func.__name__, result if print_result else '')
        return out
    return decorator
```

```

        return result
    return out
return decorator

@debug(print_result=True)
def add(x, y):
    return x + y

```

- Using only '@debug' to decorate the add() function would not work here, because debug would then receive the add() function as a 'print\_result' argument. Decorators can however manually check if the argument they received is a function and act accordingly.

## Class

```

class <name>:
    def __init__(self, a):
        self.a = a
    def __repr__(self):
        class_name = self.__class__.__name__
        return f'{class_name}({self.a!r})'
    def __str__(self):
        return str(self.a)

    @classmethod
    def get_class_name(cls):
        return cls.__name__

```

- Return value of repr() should be unambiguous and of str() readable.
- If only repr() is defined, it will also be used for str().
- Methods decorated with '@staticmethod' do not receive 'self' nor 'cls' as their first arg.

### Str() use cases:

```

print(<e1>)
f'{<e1>}'
logging.warning(<e1>)
csv.writer(<file>).writerow([<e1>])
raise Exception(<e1>)

```

### Repr() use cases:

```

print/str/repr([<e1>])
f'{<e1>!r}'
Z = dataclasses.make_dataclass('Z', ['a']); print/str/repr(Z(<e1>))
>>> <e1>

```

# Constructor Overloading

```
class <name>:
    def __init__(self, a=None):
        self.a = a
```

## Inheritance

```
class Person:
    def __init__(self, name, age):
        self.name = name
        self.age = age

class Employee(Person):
    def __init__(self, name, age, staff_num):
        super().__init__(name, age)
        self.staff_num = staff_num
```

## Multiple Inheritance

```
class A: pass
class B: pass
class C(A, B): pass
```

MRO determines the order in which parent classes are traversed when searching for a method:

```
>>> C.mro()
[<class 'C'>, <class 'A'>, <class 'B'>, <class 'object'>]
```

## Property

Pythonic way of implementing getters and setters.

```
class Person:
    @property
    def name(self):
        return ' '.join(self._name)

    @name.setter
    def name(self, value):
        self._name = value.split()
```

```
>>> person = Person()
>>> person.name = '\t Guido  van Rossum \n'
>>> person.name
'Guido van Rossum'
```

# Dataclass

Decorator that automatically generates `init()`, `repr()` and `eq()` special methods.

```
from dataclasses import dataclass, field

@dataclass(order=False, frozen=False)
class <class_name>:
    <attr_name_1>: <type>
    <attr_name_2>: <type> = <default_value>
    <attr_name_3>: list/dict/set = field(default_factory=list/dict/set)
```

- Objects can be made sortable with `'order=True'` and immutable with `'frozen=True'`.
- For object to be hashable, all attributes must be hashable and 'frozen' must be True.
- Function `field()` is needed because `'<attr_name>: list = []'` would make a list that is shared among all instances. Its `'default_factory'` argument can be any [callable](#).
- For attributes of arbitrary type use `'typing.Any'`.

Inline:

```
from dataclasses import make_dataclass

<class> = make_dataclass('<class_name>', <coll_of_attribute_names>)
<class> = make_dataclass('<class_name>', <coll_of_tuples>)
<tuple> = ('<attr_name>', <type> [, <default_value>])
```

Rest of type annotations (CPython interpreter ignores them all):

```
def func(<arg_name>: <type> [= <obj>]) -> <type>:
    <var_name>: typing.List/Set/Iterable/Sequence/Optional[<type>]
    <var_name>: typing.Dict/Tuple/Union[<type>, ...]
```

## Slots

Mechanism that restricts objects to attributes listed in 'slots' and significantly reduces their memory footprint.

```
class MyClassWithSlots:
    __slots__ = ['a']
    def __init__(self):
        self.a = 1
```

## Copy

```
from copy import copy, deepcopy

<object> = copy(<object>)
<object> = deepcopy(<object>)
```

## Duck Types

A duck type is an implicit type that prescribes a set of special methods. Any object that has those methods defined is considered a member of that duck type.

## Comparable

- If `eq()` method is not overridden, it returns `'id(self) == id(other)'`, which is the same as `'self is other'`.
- That means all objects compare not equal by default.
- Only the left side object has `eq()` method called, unless it returns `NotImplemented`, in which case the right object is consulted. `False` is returned if both return `NotImplemented`.
- `Ne()` automatically works on any object that has `eq()` defined.

```
class MyComparable:
    def __init__(self, a):
        self.a = a
    def __eq__(self, other):
        if isinstance(other, type(self)):
            return self.a == other.a
        return NotImplemented
```

## Hashable

- Hashable object needs both `hash()` and `eq()` methods and its hash value should never change.
- Hashable objects that compare equal must have the same hash value, meaning default `hash()` that returns `'id(self)'` will not do.
- That is why Python automatically makes classes unhashable if you only implement `eq()`.

```
class MyHashable:
    def __init__(self, a):
        self._a = a
    @property
    def a(self):
        return self._a
    def __eq__(self, other):
        if isinstance(other, type(self)):
            return self.a == other.a
        return NotImplemented
    def __hash__(self):
        return hash(self.a)
```

## Sortable

- With `'total_ordering'` decorator, you only need to provide `eq()` and one of `lt()`, `gt()`, `le()` or `ge()` special methods and the rest will be automatically generated.
- Functions `sorted()` and `min()` only require `lt()` method, while `max()` only requires `gt()`. However, it is best to define them all so that confusion doesn't arise in other contexts.
- When two lists, strings or dataclasses are compared, their values get compared in order until a pair of unequal values is found. The comparison of this two values is then returned. The shorter sequence is considered smaller in case of all values being equal.

```

from functools import total_ordering

@total_ordering
class MySortable:
    def __init__(self, a):
        self.a = a
    def __eq__(self, other):
        if isinstance(other, type(self)):
            return self.a == other.a
        return NotImplemented
    def __lt__(self, other):
        if isinstance(other, type(self)):
            return self.a < other.a
        return NotImplemented

```

## Iterator

- Any object that has methods `next()` and `iter()` is an iterator.
- `Next()` should return next item or raise `StopIteration`.
- `Iter()` should return 'self'.

```

class Counter:
    def __init__(self):
        self.i = 0
    def __next__(self):
        self.i += 1
        return self.i
    def __iter__(self):
        return self

```

```

>>> counter = Counter()
>>> next(counter), next(counter), next(counter)
(1, 2, 3)

```

## Python has many different iterator objects:

- Sequence iterators returned by the [iter\(\)](#) function, such as `list_iterator` and `set_iterator`.
- Objects returned by the [itertools](#) module, such as `count`, `repeat` and `cycle`.
- Generators returned by the [generator functions](#) and [generator expressions](#).
- File objects returned by the [open\(\)](#) function, etc.

## Callable

- All functions and classes have a `call()` method, hence are callable.
- When this cheatsheet uses '`<function>`' as an argument, it actually means '`<callable>`'.

```
class Counter:
    def __init__(self):
        self.i = 0
    def __call__(self):
        self.i += 1
        return self.i
```

```
>>> counter = Counter()
>>> counter(), counter(), counter()
(1, 2, 3)
```

## Context Manager

- Enter() should lock the resources and optionally return an object.
- Exit() should release the resources.
- Any exception that happens inside the with block is passed to the exit() method.
- If it wishes to suppress the exception it must return a true value.

```
class MyOpen:
    def __init__(self, filename):
        self.filename = filename
    def __enter__(self):
        self.file = open(self.filename)
        return self.file
    def __exit__(self, exc_type, exception, traceback):
        self.file.close()
```

```
>>> with open('test.txt', 'w') as file:
...     file.write('Hello world!')
>>> with MyOpen('test.txt') as file:
...     print(file.read())
Hello world!
```

## Iterable Duck Types

### Iterable

- Only required method is iter(). It should return an iterator of object's items.
- Contains() automatically works on any object that has iter() defined.

```
class MyIterable:
    def __init__(self, a):
        self.a = a
    def __iter__(self):
        return iter(self.a)
    def __contains__(self, el):
        return el in self.a
```

```
>>> obj = MyIterable([1, 2, 3])
>>> [e1 for e1 in obj]
[1, 2, 3]
>>> 1 in obj
True
```

## Collection

- Only required methods are `iter()` and `len()`.
- This cheatsheet actually means '`<iterable>`' when it uses '`<collection>`'.
- I chose not to use the name 'iterable' because it sounds scarier and more vague than 'collection'. The only drawback of this decision is that a reader could think a certain function doesn't accept iterators when it does, since iterators are the only built-in objects that are iterable but are not collections.

```
class MyCollection:
    def __init__(self, a):
        self.a = a
    def __iter__(self):
        return iter(self.a)
    def __contains__(self, e1):
        return e1 in self.a
    def __len__(self):
        return len(self.a)
```

## Sequence

- Only required methods are `len()` and `getitem()`.
- `Getitem()` should return an item at the passed index or raise `IndexError`.
- `Iter()` and `contains()` automatically work on any object that has `getitem()` defined.
- `Reversed()` automatically works on any object that has `len()` and `getitem()` defined.

```
class MySequence:
    def __init__(self, a):
        self.a = a
    def __iter__(self):
        return iter(self.a)
    def __contains__(self, e1):
        return e1 in self.a
    def __len__(self):
        return len(self.a)
    def __getitem__(self, i):
        return self.a[i]
    def __reversed__(self):
        return reversed(self.a)
```

## Discrepancies between glossary definitions and abstract base classes:

- Glossary defines iterable as any object with `iter()` or `getitem()` and sequence as any object with `len()` and `getitem()`. It does not define collection.
- Passing ABC Iterable to `isinstance()` or `issubclass()` checks whether object/class has method `iter()`, while ABC Collection checks for `iter()`, `contains()` and `len()`.

## ABC Sequence

- It's a richer interface than the basic sequence.
- Extending it generates `iter()`, `contains()`, `reversed()`, `index()` and `count()`.
- Unlike `'abc.Iterable'` and `'abc.Collection'`, it is not a duck type. That is why `'issubclass(MySequence, abc.Sequence)'` would return `False` even if `MySequence` had all the methods defined. It however recognizes `list`, `tuple`, `range`, `str`, `bytes`, `bytearray`, `memoryview` and `deque`, because they are registered as `Sequence`'s virtual subclasses.

```
from collections import abc

class MyAbcSequence(abc.Sequence):
    def __init__(self, a):
        self.a = a
    def __len__(self):
        return len(self.a)
    def __getitem__(self, i):
        return self.a[i]
```

### Table of required and automatically available special methods:

	Iterable	Collection	Sequence	abc.Sequence
<code>iter()</code>	REQ	REQ	Yes	Yes
<code>contains()</code>	Yes	Yes	Yes	Yes
<code>len()</code>		REQ	REQ	REQ
<code>getitem()</code>			REQ	REQ
<code>reversed()</code>			Yes	Yes
<code>index()</code>				Yes
<code>count()</code>				Yes

- Other ABCs that generate missing methods are: `MutableSequence`, `Set`, `MutableSet`, `Mapping` and `MutableMapping`.
- Names of their required methods are stored in `'<abc>.__abstractmethods__'`.

## Enum

```
from enum import Enum, auto
```

```
class <enum_name>(Enum):
    <member_name_1> = <value_1>
    <member_name_2> = <value_2_a>, <value_2_b>
    <member_name_3> = auto()
```

- If there are no numeric values before `auto()`, it returns 1.
- Otherwise it returns an increment of the last numeric value.

```

<member> = <enum>.<member_name>           # Returns a member.
<member> = <enum>['<member_name>']         # Returns a member or raises
KeyError.
<member> = <enum>(<value>)                 # Returns a member or raises
ValueError.
<str>     = <member>.name                  # Returns member's name.
<obj>     = <member>.value                # Returns member's value.

```

```

list_of_members = list(<enum>)
member_names    = [a.name for a in <enum>]
member_values   = [a.value for a in <enum>]
random_member   = random.choice(list(<enum>))

```

```

def get_next_member(member):
    members = list(member.__class__)
    index   = (members.index(member) + 1) % len(members)
    return members[index]

```

## Inline

```

Cutlery = Enum('Cutlery', 'fork knife spoon')
Cutlery = Enum('Cutlery', ['fork', 'knife', 'spoon'])
Cutlery = Enum('Cutlery', {'fork': 1, 'knife': 2, 'spoon': 3})

```

## User-defined functions cannot be values, so they must be wrapped:

```

from functools import partial
LogicOp = Enum('LogicOp', {'AND': partial(lambda l, r: l and r),
                           'OR':  partial(lambda l, r: l or r)})

```

- Member names are in all caps because trying to access a member that is named after a reserved keyword raises `SyntaxError`.

## Exceptions

### Basic Example

```

try:
    <code>
except <exception>:
    <code>

```

### Complex Example

```

try:
    <code_1>
except <exception_a>:
    <code_2_a>
except <exception_b>:
    <code_2_b>
else:
    <code_2_c>
finally:
    <code_3>

```

- Code inside the `'else'` block will only be executed if `'try'` block had no exceptions.
- Code inside the `'finally'` block will always be executed (unless a signal is received).

## Catching Exceptions

```

except <exception>:
except <exception> as <name>:
except (<exception>, [...]):
except (<exception>, [...]) as <name>:

```

- Also catches subclasses of the exception.
- Use `'traceback.print_exc()'` to print the error message to stderr.
- Use `'print(<name>)'` to print just the cause of the exception (its arguments).

## Raising Exceptions

```

raise <exception>
raise <exception>()
raise <exception>(<el> [, ...])

```

### Re-raising caught exception:

```

except <exception> as <name>:
    ...
    raise

```

## Exception Object

```

arguments = <name>.args
exc_type = <name>.__class__
filename = <name>.__traceback__.tb_frame.f_code.co_filename
func_name = <name>.__traceback__.tb_frame.f_code.co_name
line = linecache.getline(filename, <name>.__traceback__.tb_lineno)
traceback = ''.join(traceback.format_tb(<name>.__traceback__))
error_msg = ''.join(traceback.format_exception(exc_type, <name>,
<name>.__traceback__))

```

# Built-in Exceptions

```
BaseException
+-- SystemExit          # Raised by the sys.exit() function.
+-- KeyboardInterrupt  # Raised when the user hits the interrupt key
                        (ctrl-c).
+-- Exception           # User-defined exceptions should be derived
                        from this class.
    +-- ArithmeticError  # Base class for arithmetic errors.
    |   +-- ZeroDivisionError # Raised when dividing by zero.
    +-- AttributeError    # Raised when an attribute is missing.
    +-- EOFError          # Raised by input() when it hits end-of-file
                        condition.
    +-- LookupError       # Raised when a look-up on a collection fails.
    |   +-- IndexError     # Raised when a sequence index is out of
                        range.
    |   +-- KeyError       # Raised when a dictionary key or set element
                        is missing.
    +-- NameError         # Raised when an object is missing.
    +-- OSError           # Errors such as "file not found" or "disk
                        full" (see Open).
    |   +-- FileNotFoundError # When a file or directory is requested but
                        doesn't exist.
    +-- RuntimeError      # Raised by errors that don't fall into other
                        categories.
    |   +-- RecursionError  # Raised when the maximum recursion depth is
                        exceeded.
    +-- StopIteration     # Raised by next() when run on an empty
                        iterator.
    +-- TypeError         # Raised when an argument is of wrong type.
    +-- ValueError        # When an argument is of right type but
                        inappropriate value.
    +-- UnicodeError      # Raised when encoding/decoding strings to/from
                        bytes fails.
```

## Collections and their exceptions:

	List	Set	Dict
getitem()	IndexError		KeyError
pop()	IndexError	KeyError	KeyError
remove()	ValueError	KeyError	
index()	ValueError		

## Useful built-in exceptions:

```
raise TypeError('Argument is of wrong type!')
raise ValueError('Argument is of right type but inappropriate value!')
raise RuntimeError('None of above!')
```

## User-defined Exceptions

```
class MyError(Exception): pass
class MyInputError(MyError): pass
```

## Exit

Exits the interpreter by raising `SystemExit` exception.

```
import sys
sys.exit()                # Exits with exit code 0 (success).
sys.exit(<el>)            # Prints to stderr and exits with 1.
sys.exit(<int>)           # Exits with passed exit code.
```

## Print

```
print(<el_1>, ..., sep=' ', end='\n', file=sys.stdout, flush=False)
```

- Use `'file=sys.stderr'` for messages about errors.
- Use `'flush=True'` to forcibly flush the stream.

## Pretty Print

```
from pprint import pprint
pprint(<collection>, width=80, depth=None, compact=False, sort_dicts=True)
```

- Levels deeper than `'depth'` get replaced by `'...'`.

## Input

Reads a line from user input or pipe if present.

```
<str> = input(prompt=None)
```

- Trailing newline gets stripped.
- Prompt string is printed to the standard output before reading input.
- Raises `EOFError` when user hits EOF (ctrl-d/ctrl-z↵) or input stream gets exhausted.

## Command Line Arguments

```
import sys
scripts_path = sys.argv[0]
arguments    = sys.argv[1:]
```

# Argument Parser

```
from argparse import ArgumentParser, FileType
p = ArgumentParser(description=<str>)
p.add_argument('-<short_name>', '--<name>', action='store_true') # Flag.
p.add_argument('-<short_name>', '--<name>', type=<type>)          # Option.
p.add_argument('<name>', type=<type>, nargs=1)                    # First
argument.
p.add_argument('<name>', type=<type>, nargs='+')                  # Remaining
arguments.
p.add_argument('<name>', type=<type>, nargs='*')                  # Optional
arguments.
args = p.parse_args()                                           # Exits on
error.
value = args.<name>
```

- Use `'help=<str>'` to set argument description that will be displayed in help message.
- Use `'default=<el>'` to set the default value.
- Use `'type=FileType(<mode>)'` for files. Accepts 'encoding', but not 'newline'.

## Open

Opens the file and returns a corresponding file object.

```
<file> = open(<path>, mode='r', encoding=None, newline=None)
```

- `'encoding=None'` means that the default encoding is used, which is platform dependent. Best practice is to use `'encoding="utf-8"'` whenever possible.
- `'newline=None'` means all different end of line combinations are converted to '\n' on read, while on write all '\n' characters are converted to system's default line separator.
- `'newline=""'` means no conversions take place, but input is still broken into chunks by `readline()` and `readlines()` on every '\n', '\r' and '\r\n'.

## Modes

- `'r'` - Read (default).
- `'w'` - Write (truncate).
- `'x'` - Write or fail if the file already exists.
- `'a'` - Append.
- `'w+'` - Read and write (truncate).
- `'r+'` - Read and write from the start.
- `'a+'` - Read and write from the end.
- `'t'` - Text mode (default).
- `'b'` - Binary mode (`'br'`, `'bw'`, `'bx'`, ...).

## Exceptions

- `'FileNotFoundError'` can be raised when reading with `'r'` or `'r+'`.
- `'FileExistsError'` can be raised when writing with `'x'`.
- `'IsADirectoryError'` and `'PermissionError'` can be raised by any.
- `'OSError'` is the parent class of all listed exceptions.

## File Object

```
<file>.seek(0)                # Moves to the start of the file.
<file>.seek(offset)           # Moves 'offset' chars/bytes from the start.
<file>.seek(0, 2)             # Moves to the end of the file.
<bin_file>.seek(±offset, <anchor>) # Anchor: 0 start, 1 current position, 2
end.
```

```
<str/bytes> = <file>.read(size=-1) # Reads 'size' chars/bytes or until EOF.
<str/bytes> = <file>.readline()    # Returns a line or empty string/bytes on
EOF.
<list>      = <file>.readlines()   # Returns a list of remaining lines.
<str/bytes> = next(<file>)         # Returns a line using buffer. Do not mix.
```

```
<file>.write(<str/bytes>)        # Writes a string or bytes object.
<file>.writelines(<collection>)  # Writes a coll. of strings or bytes
objects.
<file>.flush()                  # Flushes write buffer. Runs every 4096/8192
B.
```

- Methods do not add or strip trailing newlines, even `writelines()`.

## Read Text from File

```
def read_file(filename):
    with open(filename, encoding='utf-8') as file:
        return file.readlines()
```

## Write Text to File

```
def write_to_file(filename, text):
    with open(filename, 'w', encoding='utf-8') as file:
        file.write(text)
```

## Paths

```
from os import getcwd, path, listdir, scandir
from glob import glob
```

```
<str> = getcwd()                # Returns the current working directory.
<str> = path.join(<path>, ...)  # Joins two or more pathname components.
<str> = path.abspath(<path>)    # Returns absolute path.
```

<code>&lt;str&gt; = path.basename(&lt;path&gt;)</code>	# Returns final component of the path.
<code>&lt;str&gt; = path.dirname(&lt;path&gt;)</code>	# Returns path without the final component.
<code>&lt;tup.&gt; = path.splitext(&lt;path&gt;)</code>	# Splits on last period of the final component.

<code>&lt;list&gt; = listdir(path='.')</code>	# Returns filenames located at path.
<code>&lt;list&gt; = glob('&lt;pattern&gt;')</code>	# Returns paths matching the wildcard pattern.

<code>&lt;bool&gt; = path.exists(&lt;path&gt;)</code>	# Or: <code>&lt;Path&gt;.exists()</code>
<code>&lt;bool&gt; = path.isfile(&lt;path&gt;)</code>	# Or: <code>&lt;DirEntry/Path&gt;.is_file()</code>
<code>&lt;bool&gt; = path.isdir(&lt;path&gt;)</code>	# Or: <code>&lt;DirEntry/Path&gt;.is_dir()</code>

<code>&lt;stat&gt; = os.stat(&lt;path&gt;)</code>	# Or: <code>&lt;DirEntry/Path&gt;.stat()</code>
<code>&lt;real&gt; = &lt;stat&gt;.st_mtime/st_size/...</code>	# Modification time, size in bytes, ...

## DirEntry

Unlike `listdir()`, `scandir()` returns `DirEntry` objects that cache `isfile`, `isdir` and on Windows also `stat` information, thus significantly increasing the performance of code that requires it.

<code>&lt;iter&gt; = scandir(path='.')</code>	# Returns <code>DirEntry</code> objects located at path.
<code>&lt;str&gt; = &lt;DirEntry&gt;.path</code>	# Returns whole path as a string.
<code>&lt;str&gt; = &lt;DirEntry&gt;.name</code>	# Returns final component as a string.
<code>&lt;file&gt; = open(&lt;DirEntry&gt;)</code>	# Opens the file and returns a file object.

## Path Object

```
from pathlib import Path
```

<code>&lt;Path&gt; = Path(&lt;path&gt; [, ...])</code>	# Accepts strings, Paths and <code>DirEntry</code> objects.
<code>&lt;Path&gt; = &lt;path&gt; / &lt;path&gt; [/ ...]</code>	# First or second path must be a <code>Path</code> object.

<code>&lt;Path&gt; = Path()</code>	# Returns relative cwd. Also <code>Path('.')</code> .
<code>&lt;Path&gt; = Path.cwd()</code>	# Returns absolute cwd. Also
<code>Path().resolve()</code>	
<code>&lt;Path&gt; = Path.home()</code>	# Returns user's home directory (absolute).
<code>&lt;Path&gt; = Path(__file__).resolve()</code>	# Returns script's path if cwd wasn't changed.

<code>&lt;Path&gt; = &lt;Path&gt;.parent</code>	# Returns <code>Path</code> without the final component.
<code>&lt;str&gt; = &lt;Path&gt;.name</code>	# Returns final component as a string.
<code>&lt;str&gt; = &lt;Path&gt;.stem</code>	# Returns final component without extension.
<code>&lt;str&gt; = &lt;Path&gt;.suffix</code>	# Returns final component's extension.
<code>&lt;tup.&gt; = &lt;Path&gt;.parts</code>	# Returns all components as strings.

```
<iter> = <Path>.iterdir()          # Returns directory contents as Path
objects.
<iter> = <Path>.glob('<pattern>')    # Returns Paths matching the wildcard
pattern.
```

```
<str>  = str(<Path>)                # Returns path as a string.
<file> = open(<Path>)              # Opens the file and returns a file object.
```

## OS Commands

```
import os, shutil, subprocess
```

```
os.chdir(<path>)                    # Changes the current working directory.
os.mkdir(<path>, mode=0o777)         # Creates a directory. Mode is in octal.
os.makedirs(<path>, mode=0o777)     # Creates all path's dirs. Also:
`exist_ok=False`.
```

```
shutil.copy(from, to)               # Copies the file. 'to' can exist or be a dir.
shutil.copytree(from, to)           # Copies the directory. 'to' must not exist.
```

```
os.rename(from, to)                 # Renames/moves the file or directory.
os.replace(from, to)                 # Same, but overwrites 'to' if it exists.
```

```
os.remove(<path>)                   # Deletes the file.
os.rmdir(<path>)                     # Deletes the empty directory.
shutil.rmtree(<path>)                # Deletes the directory.
```

- Paths can be either strings, Paths or DirEntry objects.
- Functions report OS related errors by raising either OSError or one of its [subclasses](#).

## Shell Commands

```
<pipe> = os.popen('<command>')      # Executes command in sh/cmd and returns its
stdout pipe.
<str>   = <pipe>.read(size=-1)      # Reads 'size' chars or until EOF. Also
readline/s().
<int>   = <pipe>.close()             # Closes the pipe. Returns None on success, int
on error.
```

**Sends '1 + 1' to the basic calculator and captures its output:**

```
>>> subprocess.run('bc', input='1 + 1\n', capture_output=True, text=True)
CompletedProcess(args='bc', returncode=0, stdout='2\n', stderr='')
```

**Sends test.in to the basic calculator running in standard mode and saves its output to test.out:**

```
>>> from shlex import split
>>> os.popen('echo 1 + 1 > test.in')
>>> subprocess.run(split('bc -s'), stdin=open('test.in'),
stdout=open('test.out', 'w'))
CompletedProcess(args=['bc', '-s'], returncode=0)
>>> open('test.out').read()
'2\n'
```

## JSON

---

**Text file format for storing collections of strings and numbers.**

```
import json
<str>      = json.dumps(<object>, ensure_ascii=True, indent=None)
<object>   = json.loads(<str>)
```

### Read Object from JSON File

```
def read_json_file(filename):
    with open(filename, encoding='utf-8') as file:
        return json.load(file)
```

### Write Object to JSON File

```
def write_to_json_file(filename, an_object):
    with open(filename, 'w', encoding='utf-8') as file:
        json.dump(an_object, file, ensure_ascii=False, indent=2)
```

## Pickle

---

**Binary file format for storing Python objects.**

```
import pickle
<bytes>    = pickle.dumps(<object>)
<object>   = pickle.loads(<bytes>)
```

### Read Object from File

```
def read_pickle_file(filename):
    with open(filename, 'rb') as file:
        return pickle.load(file)
```

## Write Object to File

```
def write_to_pickle_file(filename, an_object):  
    with open(filename, 'wb') as file:  
        pickle.dump(an_object, file)
```

## CSV

Text file format for storing spreadsheets.

```
import csv
```

## Read

```
<reader> = csv.reader(<file>)           # Also: `dialect='excel', delimiter=','.  
<list>    = next(<reader>)              # Returns next row as a list of strings.  
<list>    = list(<reader>)              # Returns a list of remaining rows.
```

- File must be opened with a `'newline=""` argument, or newlines embedded inside quoted fields will not be interpreted correctly!
- For XML and binary Excel files (xlsx, xlsx and xlsb) use [Pandas](#) library.
- To print the table to console use [Tabulate](#) library.

## Write

```
<writer> = csv.writer(<file>)           # Also: `dialect='excel', delimiter=','.  
<writer>.writerow(<collection>)         # Encodes objects using `str(<el>`.  
<writer>.writerows(<coll_of_coll>)      # Appends multiple rows.
```

- File must be opened with a `'newline=""` argument, or `'\r'` will be added in front of every `'\n'` on platforms that use `'\r\n'` line endings!

## Parameters

- `'dialect'` - Master parameter that sets the default values. String or a Dialect object.
- `'delimiter'` - A one-character string used to separate fields.
- `'quotechar'` - Character for quoting fields that contain special characters.
- `'doublequote'` - Whether quotechars inside fields are/get doubled or escaped.
- `'skipinitialspace'` - Whether whitespace after delimiter gets stripped by reader.
- `'lineterminator'` - How writer terminates rows. Reader is hardcoded to `'\n'`, `'\r'`, `'\r\n'`.
- `'quoting'` - 0: As necessary, 1: All, 2: All but numbers which are read as floats, 3: None.
- `'escapechar'` - Character for escaping quotechars if doublequote is False.

## Dialects

	excel	excel-tab	unix
delimiter	','	'\t'	','
quotechar	'\"'	'\"'	'\"'
doublequote	True	True	True
skipinitialspace	False	False	False
lineterminator	'\r\n'	'\r\n'	'\n'
quoting	0	0	1
escapechar	None	None	None

## Read Rows from CSV File

```
def read_csv_file(filename, dialect='excel'):
    with open(filename, encoding='utf-8', newline='') as file:
        return list(csv.reader(file, dialect))
```

## Write Rows to CSV File

```
def write_to_csv_file(filename, rows, dialect='excel'):
    with open(filename, 'w', encoding='utf-8', newline='') as file:
        writer = csv.writer(file, dialect)
        writer.writerows(rows)
```

## SQLite

A server-less database engine that stores each database into a separate file.

### Connect

Opens a connection to the database file. Creates a new file if path doesn't exist.

```
import sqlite3
<conn> = sqlite3.connect(<path>)          # Also ':memory:'.
<conn>.close()                          # Closes the connection.
```

### Read

Returned values can be of type str, int, float, bytes or None.

```
<cursor> = <conn>.execute('<query>')      # Can raise a subclass of
sqlite3.Error.
<tuple> = <cursor>.fetchone()             # Returns next row. Also
next(<cursor>).
<list> = <cursor>.fetchall()              # Returns remaining rows. Also
list(<cursor>).
```

## Write

```
<conn>.execute('<query>')           # Can raise a subclass of
sqlite3.Error.
<conn>.commit()                     # Saves all changes since the
last commit.
<conn>.rollback()                   # Discards all changes since the
last commit.
```

Or:

```
with <conn>:                         # Exits the block with commit()
    or rollback(),
    <conn>.execute('<query>')         # depending on whether any
    exception occurred.
```

## Placeholders

- Passed values can be of type str, int, float, bytes, None, bool, datetime.date or datetime.datetime.
- Booleans will be stored and returned as ints and dates as [ISO formatted strings](#).

```
<conn>.execute('<query>', <list/tuple>)    # Replaces '?'s in query with
values.
<conn>.execute('<query>', <dict/namedtuple>) # Replaces ':<key>'s with
values.
<conn>.executemany('<query>', <coll_of_above>) # Runs execute() multiple times.
```

## Example

Values are not actually saved in this example because `'conn.commit()'` is omitted!

```
>>> conn = sqlite3.connect('test.db')
>>> conn.execute('CREATE TABLE person (person_id INTEGER PRIMARY KEY, name,
height)')
>>> conn.execute('INSERT INTO person VALUES (NULL, ?, ?)', ('Jean-Luc',
187)).lastrowid
1
>>> conn.execute('SELECT * FROM person').fetchall()
[(1, 'Jean-Luc', 187)]
```

## MySQL

Has a very similar interface, with differences listed below.

```
# $ pip3 install mysql-connector
from mysql import connector
<conn> = connector.connect(host=<str>, ...) # `user=<str>, password=<str>,
database=<str>`.
<cursor> = <conn>.cursor() # Only cursor has execute()
method.
<cursor>.execute(<query>') # Can raise a subclass of
connector.Error.
<cursor>.execute(<query>', <list/tuple>) # Replaces '%s's in query with
values.
<cursor>.execute(<query>', <dict/namedtuple>) # Replaces '%(<key>)s's with
values.
```

## Bytes

Bytes object is an immutable sequence of single bytes. Mutable version is called bytearray.

```
<bytes> = b'<str>' # Only accepts ASCII characters and
\x00-\xff.
<int> = <bytes>[<index>] # Returns an int in range from 0 to
255.
<bytes> = <bytes>[<slice>] # Returns bytes even if it has only one
element.
<bytes> = <bytes>.join(<coll_of_bytes>) # Joins elements using bytes as a
separator.
```

## Encode

```
<bytes> = bytes(<coll_of_ints>) # Ints must be in range from 0 to 255.
<bytes> = bytes(<str>, 'utf-8') # Or: <str>.encode('utf-8')
<bytes> = <int>.to_bytes(n_bytes, ...) # `byteorder='big/little',
signed=False`.
<bytes> = bytes.fromhex('<hex>') # Hex pairs can be separated by
whitespaces.
```

## Decode

```
<list> = list(<bytes>) # Returns ints in range from 0 to 255.
<str> = str(<bytes>, 'utf-8') # Or: <bytes>.decode('utf-8')
<int> = int.from_bytes(<bytes>, ...) # `byteorder='big/little',
signed=False`.
'<hex>' = <bytes>.hex() # Returns hex pairs. Accepts `sep=
<str>`.
```

## Read Bytes from File

```
def read_bytes(filename):
    with open(filename, 'rb') as file:
        return file.read()
```

## Write Bytes to File

```
def write_bytes(filename, bytes_obj):  
    with open(filename, 'wb') as file:  
        file.write(bytes_obj)
```

## Struct

- Module that performs conversions between a sequence of numbers and a bytes object.
- System's type sizes, byte order, and alignment rules are used by default.

```
from struct import pack, unpack  
<bytes> = pack('<format>', <el_1> [, ...]) # Packages arguments into bytes  
object.  
<tuple> = unpack('<format>', <bytes>)      # Use iter_unpack() for iterator of  
tuples.
```

```
>>> pack('>hhI', 1, 2, 3)  
b'\x00\x01\x00\x02\x00\x00\x00\x03'  
>>> unpack('>hhI', b'\x00\x01\x00\x02\x00\x00\x00\x03')  
(1, 2, 3)
```

## Format

For standard type sizes and manual alignment (padding) start format string with:

- '=' - System's byte order (usually little-endian).
- '<' - Little-endian.
- '>' - Big-endian (also '!').

Besides numbers, pack() and unpack() also support bytes objects as part of the sequence:

- 'C' - A bytes object with a single element. Use 'x' for pad byte.
- '<n>S' - A bytes object with n elements.

Integer types. Use a capital letter for unsigned type. Minimum and standard sizes are in brackets:

- 'b' - char (1/1)
- 'h' - short (2/2)
- 'i' - int (2/4)
- 'l' - long (4/4)
- 'q' - long long (8/8)

## Floating point types:

- 'f' - float (4/4)
- 'd' - double (8/8)

# Array

List that can only hold numbers of a predefined type. Available types and their minimum sizes in bytes are listed above. Sizes and byte order are always determined by the system.

```
from array import array
<array> = array('<typecode>', <collection>)    # Array from collection of
numbers.
<array> = array('<typecode>', <bytes>)         # Array from bytes object.
<array> = array('<typecode>', <array>)         # Treats array as a sequence of
numbers.
<bytes> = bytes(<array>)                       # Or: <array>.tobytes()
<file>.write(<array>)                          # Writes array to the binary
file.
```

## Memory View

- A sequence object that points to the memory of another object.
- Each element can reference a single or multiple consecutive bytes, depending on format.
- Order and number of elements can be changed with slicing.
- Casting only works between char and other types and uses system's sizes.
- Byte order is always determined by the system.

```
<mview> = memoryview(<bytes bytearray/array>) # Immutable if bytes, else
mutable.
<real> = <mview>[<index>] # Returns an int or a float.
<mview> = <mview>[<slice>] # Mview with rearranged elements.
<mview> = <mview>.cast('<typecode>') # Casts memoryview to the new
format.
<mview>.release() # Releases the object's memory
buffer.
```

## Decode

```
<bytes> = bytes(<mview>) # Creates a new bytes object.
<bytes> = <bytes>.join(<coll_of_mviews>) # Joins mviews using bytes object
as sep.
<array> = array('<typecode>', <mview>) # Treats mview as a sequence of
numbers.
<file>.write(<mview>) # Writes mview to the binary
file.
```

```

<list> = list(<mview>) # Returns a list of ints or floats.
<str> = str(<mview>, 'utf-8') # Treats mview as a bytes object.
<int> = int.from_bytes(<mview>, ...) # `byteorder='big/little', signed=False`.
'<hex>' = <mview>.hex() # Treats mview as a bytes object.

```

## Deque

A thread-safe list with efficient appends and pops from either side. Pronounced "deck".

```

from collections import deque
<deque> = deque(<collection>, maxlen=None)

```

```

<deque>.appendleft(<el>) # Opposite element is dropped if full.
<deque>.extendleft(<collection>) # Collection gets reversed.
<el> = <deque>.popleft() # Raises IndexError if empty.
<deque>.rotate(n=1) # Rotates elements to the right.

```

## Threading

- CPython interpreter can only run a single thread at a time.
- That is why using multiple threads won't result in a faster execution, unless at least one of the threads contains an I/O operation.

```

from threading import Thread, RLock, Semaphore, Event, Barrier
from concurrent.futures import ThreadPoolExecutor

```

## Thread

```

<Thread> = Thread(target=<function>) # Use `args=<collection>` to set the arguments.
<Thread>.start() # Starts the thread.
<bool> = <Thread>.is_alive() # Checks if the thread has finished executing.
<Thread>.join() # Waits for the thread to finish.

```

- Use `'kwargs=<dict>'` to pass keyword arguments to the function.
- Use `'daemon=True'`, or the program will not be able to exit while the thread is alive.

## Lock

```

<lock> = RLock() # Lock that can only be released by the owner.
<lock>.acquire() # Waits for the lock to be available.
<lock>.release() # Makes the lock available again.

```

Or:

```
with <lock>:                                # Enters the block by calling
    acquire(),                               # and exits it with release().
    ...
```

## Semaphore, Event, Barrier

```
<Semaphore> = Semaphore(value=1)           # Lock that can be acquired by
'value' threads.                           # Method wait() blocks until
<Event>      = Event()                     # set() is called.
set() is called.                           # wait() blocks until it's called
<Barrier>    = Barrier(n_times)            # n_times.
```

## Thread Pool Executor

- Object that manages thread execution.
- An object with the same interface called `ProcessPoolExecutor` provides true parallelism by running a separate interpreter in each process. All arguments must be [pickable](#).

```
<Exec> = ThreadPoolExecutor(max_workers=None) # Or: `with ThreadPoolExecutor()
as <name>: ...`
<Exec>.shutdown(wait=True)                  # Blocks until all threads finish
executing.
```

```
<iter> = <Exec>.map(<func>, <args_1>, ...)   # A multithreaded and non-lazy
map().
<Futr> = <Exec>.submit(<func>, <arg_1>, ...) # Starts a thread and returns its
Future object.
<bool> = <Futr>.done()                      # Checks if the thread has
finished executing.
<obj> = <Futr>.result()                     # Waits for thread to finish and
returns result.
```

## Queue

A thread-safe FIFO queue. For LIFO queue use `LifoQueue`.

```
from queue import Queue
<Queue> = Queue(maxsize=0)
```

```

<Queue>.put(<el>)                # Blocks until queue stops being
full.
<Queue>.put_nowait(<el>)          # Raises queue.Full exception if
full.
<el> = <Queue>.get()              # Blocks until queue stops being
empty.
<el> = <Queue>.get_nowait()       # Raises queue.Empty exception if
empty.

```

## Operator

Module of functions that provide the functionality of operators.

```

import operator as op
<el>      = op.add/sub/mul/truediv/floordiv/mod(<el>, <el>) # +, -, *, /, //, %
<int/set> = op.and_/or_/xor(<int/set>, <int/set>)         # &, |, ^
<bool>    = op.eq/ne/lt/le/gt/ge(<sortable>, <sortable>)  # ==, !=, <, <=, >,
>=
<func>    = op.itemgetter/attrgetter/methodcaller(<obj>) # [index/key],
.name, .name()

```

```

elementwise_sum = map(op.add, list_a, list_b)
sorted_by_second = sorted(<collection>, key=op.itemgetter(1))
sorted_by_both   = sorted(<collection>, key=op.itemgetter(1, 0))
product_of_elems = functools.reduce(op.mul, <collection>)
union_of_sets    = functools.reduce(op.or_, <coll_of_sets>)
first_element    = op.methodcaller('pop', 0)(<list>)

```

- Binary operators require objects to have `and()`, `or()`, `xor()` and `invert()` special methods, unlike logical operators that work on all types of objects.
- Also: `'<bool> = <bool> &|^ <bool>'` and `'<int> = <bool> &|^ <int>'`.

## Introspection

Inspecting code at runtime.

### Variables

```

<list> = dir()                # Names of local variables (incl.
functions).
<dict> = vars()               # Dict of local variables. Also
locals().
<dict> = globals()           # Dict of global variables.

```

### Attributes

```

<list> = dir(<object>)                # Names of object's attributes (incl.
methods).
<dict> = vars(<object>)                # Dict of writable attributes. Also
<obj>.__dict__.
<bool> = hasattr(<object>, '<attr_name>') # Checks if getattr() raises an
AttributeError.
value = getattr(<object>, '<attr_name>') # Raises AttributeError if attribute
is missing.
setattr(<object>, '<attr_name>', value)  # Only works on objects with
'__dict__' attribute.
delattr(<object>, '<attr_name>')        # Same. Also `del <object>.`
<attr_name>`.

```

## Parameters

```

from inspect import signature
<sig> = signature(<function>)          # Function's Signature object.
<dict> = <Sig>.parameters              # Dict of function's Parameter
objects.
<str> = <Param>.name                   # Parameter's name.
<memb> = <Param>.kind                  # Member of ParameterKind enum.

```

## Metaprogramming

Code that generates code.

### Type

Type is the root class. If only passed an object it returns its type (class). Otherwise it creates a new class.

```

<class> = type('<class_name>', <tuple_of_parents>, <dict_of_class_attributes>)

```

```

>>> z = type('Z', (), {'a': 'abcde', 'b': 12345})
>>> z = Z()

```

### Meta Class

A class that creates classes.

```

def my_meta_class(name, parents, attrs):
    attrs['a'] = 'abcde'
    return type(name, parents, attrs)

```

Or:

```

class MyMetaClass(type):
    def __new__(cls, name, parents, attrs):
        attrs['a'] = 'abcde'
        return type.__new__(cls, name, parents, attrs)

```

- New() is a class method that gets called before init(). If it returns an instance of its class, then that instance gets passed to init() as a 'self' argument.
- It receives the same arguments as init(), except for the first one that specifies the desired type of the returned instance (MyMetaClass in our case).
- Like in our case, new() can also be called directly, usually from a new() method of a child class (def \_\_new\_\_(cls): return super().\_\_new\_\_(cls)).
- The only difference between the examples above is that my\_meta\_class() returns a class of type type, while MyMetaClass() returns a class of type MyMetaClass.

## Metaclass Attribute

Right before a class is created it checks if it has the 'metaclass' attribute defined. If not, it recursively checks if any of his parents has it defined and eventually comes to type().

```
class MyClass(metaclass=MyMetaClass):
    b = 12345
```

```
>>> MyClass.a, MyClass.b
('abcde', 12345)
```

## Type Diagram

```
type(MyClass)      == MyMetaClass      # MyClass is an instance of MyMetaClass.
type(MyMetaClass) == type              # MyMetaClass is an instance of type.
```

```
+-----+-----+
|  Classes  | Metaclasses |
+-----+-----+
|  MyClass --> MyMetaClass |
|           |      v      |
|  object  <----> type <+  |
|           |      ^  +--+ |
|    str  -----+         |
+-----+-----+
```

## Inheritance Diagram

```
MyClass.__base__    == object          # MyClass is a subclass of object.
MyMetaClass.__base__ == type           # MyMetaClass is a subclass of type.
```

```
+-----+-----+
|  Classes  | Metaclasses |
+-----+-----+
|  MyClass  | MyMetaClass |
|    v      |    v      |
|  object <----- type   |
|    ^      |           |
|    str    |           |
+-----+-----+
```

# Eval

```
>>> from ast import literal_eval
>>> literal_eval('[1, 2, 3]')
[1, 2, 3]
>>> literal_eval('1 + 2')
ValueError: malformed node or string
```

## Coroutines

- Coroutines have a lot in common with threads, but unlike threads, they only give up control when they call another coroutine and they don't use as much memory.
- Coroutine definition starts with `'async'` and its call with `'await'`.
- `'asyncio.run(<coroutine>)'` is the main entry point for asynchronous programs.
- Functions `wait()`, `gather()` and `as_completed()` can be used when multiple coroutines need to be started at the same time.
- Asyncio module also provides its own [Queue](#), [Event](#), [Lock](#) and [Semaphore](#) classes.

Runs a terminal game where you control an asterisk that must avoid numbers:

```
import asyncio, collections, curses, curses.textpad, enum, random

P = collections.namedtuple('P', 'x y')          # Position
D = enum.Enum('D', 'n e s w')                  # Direction
W, H = 15, 7                                   # Width, Height

def main(screen):
    curses.curs_set(0)                          # Makes cursor invisible.
    screen.nodelay(True)                       # Makes getch() non-blocking.
    asyncio.run(main_coroutine(screen))         # Starts running asyncio code.

async def main_coroutine(screen):
    state = {'*': P(0, 0), **{id_: P(W//2, H//2) for id_ in range(10)}}
    moves = asyncio.Queue()
    coros = (*(random_controller(id_, moves) for id_ in range(10)),
              human_controller(screen, moves), model(moves, state), view(state,
screen))
    await asyncio.wait(coros, return_when=asyncio.FIRST_COMPLETED)

async def random_controller(id_, moves):
    while True:
        d = random.choice(list(D))
        moves.put_nowait((id_, d))
        await asyncio.sleep(random.triangular(0.01, 0.65))

async def human_controller(screen, moves):
    while True:
        ch = screen.getch()
        key_mappings = {258: D.s, 259: D.n, 260: D.w, 261: D.e}
        if ch in key_mappings:
            moves.put_nowait(('*', key_mappings[ch]))
        await asyncio.sleep(0.005)
```

```

async def model(moves, state):
    while state['*'] not in (state[id_] for id_ in range(10)):
        id_, d = await moves.get()
        x, y = state[id_]
        deltas = {D.n: P(0, -1), D.e: P(1, 0), D.s: P(0, 1), D.w: P(-1, 0)}
        state[id_] = P((x + deltas[d].x) % W, (y + deltas[d].y) % H)

async def view(state, screen):
    offset = P(curses.COLS//2 - W//2, curses.LINES//2 - H//2)
    while True:
        screen.erase()
        curses.textpad.rectangle(screen, offset.y-1, offset.x-1, offset.y+H,
offset.x+W)
        for id_, p in state.items():
            screen.addstr(offset.y + (p.y - state['*'].y + H//2) % H,
                        offset.x + (p.x - state['*'].x + W//2) % W, str(id_))
        await asyncio.sleep(0.005)

if __name__ == '__main__':
    curses.wrapper(main)

```

## Libraries

### Progress Bar

```

# $ pip3 install tqdm
>>> from tqdm import tqdm
>>> from time import sleep
>>> for el in tqdm([1, 2, 3], desc='Processing'):
...     sleep(1)
Processing: 100%|████████████████████| 3/3 [00:03<00:00, 1.00s/it]

```

### Plot

```

# $ pip3 install matplotlib
import matplotlib.pyplot as plt
plt.plot(<x_data>, <y_data> [, label=<str>]) # Or: plt.plot(<y_data>)
plt.legend() # Adds a legend.
plt.savefig(<path>) # Saves the figure.
plt.show() # Displays the figure.
plt.clf() # Clears the figure.

```

### Table

## Prints a CSV file as an ASCII table:

```
# $ pip3 install tabulate
import csv, tabulate
with open('test.csv', encoding='utf-8', newline='') as file:
    rows = csv.reader(file)
    header = next(rows)
    table = tabulate.tabulate(rows, header)
print(table)
```

## Curses

### Runs a basic file explorer in the terminal:

```
from curses import wrapper, ascii, A_REVERSE, KEY_DOWN, KEY_UP, KEY_LEFT,
KEY_RIGHT, KEY_ENTER
from os import listdir, path, chdir

def main(screen):
    ch, first, selected, paths = 0, 0, 0, listdir()
    while ch != ascii.ESC:
        height, _ = screen.getmaxyx()
        screen.erase()
        for y, filename in enumerate(paths[first : first+height]):
            screen.addstr(y, 0, filename, A_REVERSE * (selected == first + y))
        ch = screen.getch()
        selected += (ch == KEY_DOWN) - (ch == KEY_UP)
        selected = max(0, min(len(paths)-1, selected))
        first += (first <= selected - height) - (first > selected)
        if ch in [KEY_LEFT, KEY_RIGHT, KEY_ENTER, 10, 13]:
            new_dir = '..' if ch == KEY_LEFT else paths[selected]
            if path.isdir(new_dir):
                chdir(new_dir)
                first, selected, paths = 0, 0, listdir()

if __name__ == '__main__':
    wrapper(main)
```

## Logging

```
# $ pip3 install loguru
from loguru import logger
```

```
logger.add('debug_{time}.log', colorize=True) # Connects a log file.
logger.add('error_{time}.log', level='ERROR') # Another file for errors or
higher.
logger.<level>('A logging message.')
```

- **Levels:** 'debug', 'info', 'success', 'warning', 'error', 'critical'.

## Exceptions

Exception description, stack trace and values of variables are appended automatically.

```
try:
    ...
except <exception>:
    logger.exception('An error happened.')
```

## Rotation

Argument that sets a condition when a new log file is created.

```
rotation=<int>|<datetime.timedelta>|<datetime.time>|<str>
```

- '`<int>`' - Max file size in bytes.
- '`<timedelta>`' - Max age of a file.
- '`<time>`' - Time of day.
- '`<str>`' - Any of above as a string: '100 MB', '1 month', 'monday at 12:00', ...

## Retention

Sets a condition which old log files get deleted.

```
retention=<int>|<datetime.timedelta>|<str>
```

- '`<int>`' - Max number of files.
- '`<timedelta>`' - Max age of a file.
- '`<str>`' - Max age as a string: '1 week, 3 days', '2 months', ...

## Scraping

Scrapes Python's URL, version number and logo from its Wikipedia page:

```
# $ pip3 install requests beautifulsoup4
import requests, bs4, os, sys

WIKI_URL = 'https://en.wikipedia.org/wiki/Python_(programming_language)'
try:
    html = requests.get(WIKI_URL).text
    document = bs4.BeautifulSoup(html, 'html.parser')
    table = document.find('table', class_='infobox vevent')
    python_url = table.find('th', text='website').next_sibling.a['href']
    version = table.find('th', text='Stable
release').next_sibling.strings.__next__()
    logo_url = table.find('img')['src']
    logo = requests.get(f'https://{logo_url}').content
    filename = os.path.basename(logo_url)
    with open(filename, 'wb') as file:
        file.write(logo)
    print(f'{python_url}, {version}, file://{os.path.abspath(filename)}')
except requests.exceptions.ConnectionError:
```

```
print("You've got problems with connection.", file=sys.stderr)
```

## Web

---

```
# $ pip3 install bottle
from bottle import run, route, static_file, template, post, request, response
import json
```

## Run

```
run(host='localhost', port=8080)      # Runs locally.
run(host='0.0.0.0', port=80)         # Runs globally.
```

## Static Request

```
@route('/img/<filename>')
def send_file(filename):
    return static_file(filename, root='img_dir/')
```

## Dynamic Request

```
@route('/<sport>')
def send_html(sport):
    return template('<h1>{{title}}</h1>', title=sport)
```

## REST Request

```
@post('/<sport>/odds')
def send_json(sport):
    team = request.forms.get('team')
    response.headers['Content-Type'] = 'application/json'
    response.headers['Cache-Control'] = 'no-cache'
    return json.dumps({'team': team, 'odds': [2.09, 3.74, 3.68]})
```

## Test:

```
# $ pip3 install requests
>>> import threading, requests
>>> threading.Thread(target=run, daemon=True).start()
>>> url = 'http://localhost:8080/football/odds'
>>> request_data = {'team': 'arsenal f.c.'}
>>> response = requests.post(url, data=request_data)
>>> response.json()
{'team': 'arsenal f.c.', 'odds': [2.09, 3.74, 3.68]}
```

## Profiling

---

## Stopwatch

```
from time import time
start_time = time()                # Seconds since the Epoch.
...
duration = time() - start_time
```

## High performance:

```
from time import perf_counter
start_time = perf_counter()        # Seconds since the restart.
...
duration = perf_counter() - start_time
```

## Timing a Snippet

```
>>> from timeit import timeit
>>> timeit(''.join(str(i) for i in range(100))",
...       number=10000, globals=globals(), setup='pass')
0.34986
```

## Profiling by Line

```
# $ pip3 install line_profiler memory_profiler
@profile
def main():
    a = [*range(10000)]
    b = {*range(10000)}
main()
```

```
$ kernprof -lv test.py
Line #    Hits      Time    Per Hit   % Time  Line Contents
=====
      1                                @profile
      2                                def main():

```

# Call Graph

Generates a PNG image of the call graph with highlighted bottlenecks:

```
# $ pip3 install pycallgraph2
# $ apt install graphviz
import pycallgraph2 as cg, datetime
filename = f'profile-{datetime.datetime.now():%Y%m%d%H%M%S}.png'
drawer = cg.output.GraphvizOutput(output_file=filename)
with cg.PyCallGraph(drawer):
    <code_to_be_profiled>
```

# NumPy

Array manipulation mini-language. It can run up to one hundred times faster than the equivalent Python code. An even faster alternative that runs on a GPU is called CuPy.

```
# $ pip3 install numpy
import numpy as np
```

```
<array> = np.array(<list/list_of_lists>)
<array> = np.arange(from_inclusive, to_exclusive, ±step_size)
<array> = np.ones(<shape>)
<array> = np.random.randint(from_inclusive, to_exclusive, <shape>)
```

```
<array>.shape = <shape>
<view> = <array>.reshape(<shape>)
<view> = np.broadcast_to(<array>, <shape>)
```

```
<array> = <array>.sum(axis)
indexes = <array>.argmin(axis)
```

- **Shape is a tuple of dimension sizes.**
- **Axis is an index of the dimension that gets aggregated. Leftmost dimension has index 0.**

# Indexing

```
<el> = <2d_array>[row_index, column_index]
<1d_view> = <2d_array>[row_index]
<1d_view> = <2d_array>[:, column_index]
```

```
<1d_array> = <2d_array>[row_indexes, column_indexes]
<2d_array> = <2d_array>[row_indexes]
<2d_array> = <2d_array>[:, column_indexes]
```

```
<2d_bools> = <2d_array> ><== <el>
<1d_array> = <2d_array>[<2d_bools>]
```

# Broadcasting

Broadcasting is a set of rules by which NumPy functions operate on arrays of different sizes and/or dimensions.

```
left  = [[0.1], [0.6], [0.8]]      # Shape: (3, 1)
right = [ 0.1 ,  0.6 ,  0.8 ]      # Shape: (3)
```

**1. If array shapes differ in length, left-pad the shorter shape with ones:**

```
left  = [[0.1], [0.6], [0.8]]      # Shape: (3, 1)
right = [[0.1 ,  0.6 ,  0.8]]      # Shape: (1, 3) <- !
```

**2. If any dimensions differ in size, expand the ones that have size 1 by duplicating their elements:**

```
left  = [[0.1, 0.1, 0.1], [0.6, 0.6, 0.6], [0.8, 0.8, 0.8]] # Shape: (3, 3) <- !
right = [[0.1, 0.6, 0.8], [0.1, 0.6, 0.8], [0.1, 0.6, 0.8]] # Shape: (3, 3) <- !
```

**3. If neither non-matching dimension has size 1, raise an error.**

## Example

For each point returns index of its nearest point ( [0.1, 0.6, 0.8] => [1, 2, 1] ):

```
>>> points = np.array([0.1, 0.6, 0.8])
[ 0.1,  0.6,  0.8]
>>> wrapped_points = points.reshape(3, 1)
[[ 0.1],
 [ 0.6],
 [ 0.8]]
>>> distances = wrapped_points - points
[[ 0. , -0.5, -0.7],
 [ 0.5,  0. , -0.2],
 [ 0.7,  0.2,  0. ]]
>>> distances = np.abs(distances)
[[ 0. ,  0.5,  0.7],
 [ 0.5,  0. ,  0.2],
 [ 0.7,  0.2,  0. ]]
>>> i = np.arange(3)
[0, 1, 2]
>>> distances[i, i] = np.inf
[[ inf,  0.5,  0.7],
 [ 0.5,  inf,  0.2],
 [ 0.7,  0.2,  inf]]
>>> distances.argmin(1)
[1, 2, 1]
```

# Image

```
# $ pip3 install pillow
from PIL import Image
```

```
<Image> = Image.new('<mode>', (width, height)) # Also: `color=<int/tuple/str>`.
<Image> = Image.open(<path>)                  # Identifies format based on
file contents.
<Image> = <Image>.convert('<mode>')            # Converts image to the new
mode.
<Image>.save(<path>)                           # Selects format based on the
path extension.
<Image>.show()                                 # Opens image in default preview
app.
```

```
<int/tuple> = <Image>.getpixel((x, y))         # Returns a pixel.
<Image>.putpixel((x, y), <int/tuple>)         # Writes a pixel to the image.
<ImagingCore> = <Image>.getdata()             # Returns a flattened sequence
of pixels.
<Image>.putdata(<list/ImagingCore>)           # Writes a flattened sequence of
pixels.
<Image>.paste(<Image>, (x, y))                # Writes an image to the image.
```

```
<2d_array> = np.array(<Image_L>)               # Creates NumPy array from
greyscale image.
<3d_array> = np.array(<Image_RGB>)             # Creates NumPy array from color
image.
<Image>      = Image.fromarray(<array>)        # Creates image from NumPy array
of floats.
```

## Modes

- `'1'` - 1-bit pixels, black and white, stored with one pixel per byte.
- `'L'` - 8-bit pixels, greyscale.
- `'RGB'` - 3x8-bit pixels, true color.
- `'RGBA'` - 4x8-bit pixels, true color with transparency mask.
- `'HSV'` - 3x8-bit pixels, Hue, Saturation, Value color space.

## Examples

**Creates a PNG image of a rainbow gradient:**

```
WIDTH, HEIGHT = 100, 100
n_pixels = WIDTH * HEIGHT
hues = (255 * i/n_pixels for i in range(n_pixels))
img = Image.new('HSV', (WIDTH, HEIGHT))
img.putdata([(int(h), 255, 255) for h in hues])
img.convert('RGB').save('test.png')
```

## Adds noise to a PNG image:

```
from random import randint
add_noise = lambda value: max(0, min(255, value + randint(-20, 20)))
img = Image.open('test.png').convert('HSV')
img.putdata([(add_noise(h), s, v) for h, s, v in img.getdata()])
img.convert('RGB').save('test.png')
```

## Image Draw

```
from PIL import ImageDraw
<ImageDraw> = ImageDraw.Draw(<Image>)
```

```
<ImageDraw>.point((x, y))
<ImageDraw>.line((x1, y1, x2, y2 [, ...]))
<ImageDraw>.arc((x1, y1, x2, y2), from_deg, to_deg)
<ImageDraw>.rectangle((x1, y1, x2, y2))
<ImageDraw>.polygon((x1, y1, x2, y2 [, ...]))
<ImageDraw>.ellipse((x1, y1, x2, y2))
```

- Use `'fill=<color>'` to set the primary color.
- Use `'width=<int>'` to set the width of lines or contours.
- Use `'outline=<color>'` to set the color of the contours.
- Colors can be specified as an int, tuple, `'#rrggbb[aa]'` string or a color name.

## Animation

### Creates a GIF of a bouncing ball:

```
# $ pip3 install imageio
from PIL import Image, ImageDraw
import imageio
WIDTH, HEIGHT, R = 126, 126, 10
frames = []
for velocity in range(1, 16):
    y = sum(range(velocity))
    frame = Image.new('L', (WIDTH, HEIGHT))
    draw = ImageDraw.Draw(frame)
    draw.ellipse((WIDTH/2-R, y, WIDTH/2+R, y+R*2), fill='white')
    frames.append(frame)
frames += reversed(frames[1:-1])
imageio.mimsave('test.gif', frames, duration=0.03)
```

## Audio

```
import wave
```

```

<Wave_read> = wave.open('<path>', 'rb')           # Opens the WAV file.
framerate    = <Wave_read>.getframerate()         # Number of frames per second.
nchannels    = <Wave_read>.getnchannels()         # Number of samples per frame.
sampwidth    = <Wave_read>.getsampwidth()         # Sample size in bytes.
nframes      = <Wave_read>.getnframes()           # Number of frames.
<params>     = <Wave_read>.getparams()            # Immutable collection of above.
<bytes>      = <Wave_read>.readframes(nframes)    # Returns next 'nframes' frames.

```

```

<Wave_write> = wave.open('<path>', 'wb')           # Truncates existing file.
<Wave_write>.setframerate(<int>)                 # 44100 for CD, 48000 for video.
<Wave_write>.setnchannels(<int>)                 # 1 for mono, 2 for stereo.
<Wave_write>.setsampwidth(<int>)                 # 2 for CD quality sound.
<Wave_write>.setparams(<params>)                 # Sets all parameters.
<Wave_write>.writeframes(<bytes>)                # Appends frames to the file.

```

- Bytes object contains a sequence of frames, each consisting of one or more samples.
- In a stereo signal, the first sample of a frame belongs to the left channel.
- Each sample consists of one or more bytes that, when converted to an integer, indicate the displacement of a speaker membrane at a given moment.
- If sample width is one byte, then the integer should be encoded unsigned.
- For all other sizes, the integer should be encoded signed with little-endian byte order.

## Sample Values

sampwidth	min	zero	max
1	0	128	255
2	-32768	0	32767
3	-8388608	0	8388607
4	-2147483648	0	2147483647

## Read Float Samples from WAV File

```

def read_wav_file(filename):
    def get_int(bytes_obj):
        an_int = int.from_bytes(bytes_obj, 'little', signed=(sampwidth != 1))
        return an_int - 128 * (sampwidth == 1)
    with wave.open(filename, 'rb') as file:
        sampwidth = file.getsampwidth()
        frames = file.readframes(-1)
        bytes_samples = (frames[i : i+sampwidth] for i in range(0, len(frames),
            sampwidth))
        return [get_int(b) / pow(2, sampwidth * 8 - 1) for b in bytes_samples]

```

## Write Float Samples to WAV File

```
def write_to_wav_file(filename, float_samples, nchannels=1, sampwidth=2,
framerate=44100):
    def get_bytes(a_float):
        a_float = max(-1, min(1 - 2e-16, a_float))
        a_float += sampwidth == 1
        a_float *= pow(2, sampwidth * 8 - 1)
        return int(a_float).to_bytes(sampwidth, 'little', signed=(sampwidth !=
1))
    with wave.open(filename, 'wb') as file:
        file.setnchannels(nchannels)
        file.setsampwidth(sampwidth)
        file.setframerate(framerate)
        file.writeframes(b''.join(get_bytes(f) for f in float_samples))
```

## Examples

### Saves a 440 Hz sine wave to a mono WAV file:

```
from math import pi, sin
samples_f = (sin(i * 2 * pi * 440 / 44100) for i in range(100000))
write_to_wav_file('test.wav', samples_f)
```

### Adds noise to a mono WAV file:

```
from random import random
add_noise = lambda value: value + (random() - 0.5) * 0.03
samples_f = (add_noise(f) for f in read_wav_file('test.wav'))
write_to_wav_file('test.wav', samples_f)
```

### Plays a WAV file:

```
# $ pip3 install simpleaudio
from simpleaudio import play_buffer
with wave.open('test.wav', 'rb') as file:
    p = file.getparams()
    frames = file.readframes(-1)
    play_buffer(frames, p.nchannels, p.sampwidth, p.framerate)
```

## Text to Speech

```
# $ pip3 install pyttsx3
import pyttsx3
engine = pyttsx3.init()
engine.say('Sally sells seashells by the seashore.')
engine.runAndWait()
```

## Synthesizer

## Plays Popcorn by Gershon Kingsley:

```
# $ pip3 install simpleaudio
import math, struct, simpleaudio
from itertools import repeat, chain
F = 44100
P1 = '71J,69J,,71J,66J,,62J,66J,,59J,, '
P2 = '71J,73J,,74J,73J,,74J,,71J,,73J,71J,,73J,,69J,,71J,69J,,71J,,67J,,71J,, '
get_pause = lambda seconds: repeat(0, int(seconds * F))
sin_f = lambda i, hz: math.sin(i * 2 * math.pi * hz / F)
get_wave = lambda hz, seconds: (sin_f(i, hz) for i in range(int(seconds * F)))
get_hz = lambda key: 8.176 * 2 ** (int(key) / 12)
parse_note = lambda note: (get_hz(note[:2]), 1/4 if 'J' in note else 1/8)
get_samples = lambda note: get_wave(*parse_note(note)) if note else
get_pause(1/8)
samples_f = chain.from_iterable(get_samples(n) for n in f'{P1},{P1},
{P2}'.split(','))
samples_b = b''.join(struct.pack('<h', int(f * 30000)) for f in samples_f)
simpleaudio.play_buffer(samples_b, 1, 2, F)
```

## Pygame

### Basic Example

```
# $ pip3 install pygame
import pygame as pg
pg.init()
screen = pg.display.set_mode((500, 500))
rect = pg.Rect(240, 240, 20, 20)
while all(event.type != pg.QUIT for event in pg.event.get()):
    deltas = {pg.K_UP: (0, -1), pg.K_RIGHT: (1, 0), pg.K_DOWN: (0, 1),
pg.K_LEFT: (-1, 0)}
    for ch, is_pressed in enumerate(pg.key.get_pressed()):
        rect = rect.move(deltas[ch]) if ch in deltas and is_pressed else rect
    screen.fill((0, 0, 0))
    pg.draw.rect(screen, (255, 255, 255), rect)
    pg.display.flip()
```

## Rectangle

Object for storing rectangular coordinates.

<code>&lt;Rect&gt; = pg.Rect(x, y, width, height)</code>	# Floats get truncated into ints.
<code>&lt;int&gt; = &lt;Rect&gt;.x/y/centerx/centery/...</code>	# Top, right, bottom, left.
Allows assignments.	
<code>&lt;tup.&gt; = &lt;Rect&gt;.topleft/center/...</code>	# Topright, bottomright, bottomleft. Same.
<code>&lt;Rect&gt; = &lt;Rect&gt;.move((x, y))</code>	# Use <code>move_ip()</code> to move in-place.

```

<bool> = <Rect>.collidepoint((x, y))      # Checks if rectangle contains a
point.
<bool> = <Rect>.colliderect(<Rect>)        # Checks if two rectangles
overlap.
<int> = <Rect>.collidelist(<list_of_Rect>)  # Returns index of first
colliding Rect or -1.
<list> = <Rect>.collidelistall(<list_of_Rect>) # Returns indexes of all
colliding rectangles.

```

## Surface

Object for representing images.

```

<Surf> = pg.display.set_mode((width, height)) # Returns display surface.
<Surf> = pg.Surface((width, height), flags=0)  # New RGB surface. RGBA if
`flags=pg.SRCALPHA`.
<Surf> = pg.image.load('<path>')              # Loads the image. Format
depends on source.
<Surf> = <Surf>.subsurface(<Rect>)            # Returns a subsurface.

```

```

<Surf>.fill(color)                          # Tuple, Color('#rrggbb[aa]') or
Color(<name>).
<Surf>.set_at((x, y), color)                # Updates pixel.
<Surf>.blit(<Surf>, (x, y))                 # Draws passed surface to the
surface.

```

```

from pygame.transform import scale, ...
<Surf> = scale(<Surf>, (width, height))      # Returns scaled surface.
<Surf> = rotate(<Surf>, degrees)             # Returns rotated and scaled
surface.
<Surf> = flip(<Surf>, x_bool, y_bool)        # Returns flipped surface.

```

```

from pygame.draw import line, ...
line(<Surf>, color, (x1, y1), (x2, y2), width) # Draws a line to the surface.
arc(<Surf>, color, <Rect>, from_rad, to_rad)   # Also: ellipse(<Surf>, color,
<Rect>)
rect(<Surf>, color, <Rect>)                   # Also: polygon(<Surf>, color,
points)

```

## Font

```

<Font> = pg.font.SysFont('<name>', size)      # Loads the system font or
default if missing.
<Font> = pg.font.Font('<path>', size)        # Loads the TTF file. Pass None
for default.
<Surf> = <Font>.render(text, antialias, color) # Background color can be
specified at the end.

```

## Sound

```
<Sound> = pg.mixer.Sound('<path>')          # Loads the WAV file.
<Sound>.play()                             # Starts playing the sound.
```

## Basic Mario Brothers Example

```
import collections, dataclasses, enum, io, itertools as it, pygame as pg,
urllib.request
from random import randint

P = collections.namedtuple('P', 'x y')      # Position
D = enum.Enum('D', 'n e s w')              # Direction
W, H, MAX_S = 50, 50, P(5, 10)            # Width, Height, Max speed

def main():
    def get_screen():
        pg.init()

the bottom. |
```

	axis=0,	a 1 2 .	2		Uses 'outer'
by default.					
	join=...)	b 3 4 .	4		A series is
treated as a					
		b . 4 5	4		column. Use
l.append(sr)					
		c . 6 7	6		to add a row
instead.					
+-----+-----+-----+-----+-----+					
-----+					
	pd.concat([l, r],	x y y z			Adds columns
at the					
	axis=1,	a 1 2 . .	x y y z		right end.
Uses 'outer'					
	join=...)	b 3 4 4 5	3 4 4 5		by default.
A series is					
		c . . 6 7			treated as a
column.					
+-----+-----+-----+-----+-----+					
-----+					
	l.combine_first(r)	x y z			Adds missing
rows and					
		a 1 2 .			columns.
Also updates					
		b 3 4 5			items that
contain NaN.					
		c . 6 7			R must be a
DataFrame.					
+-----+-----+-----+-----+-----+					
-----+					

## DataFrame — Aggregate, Transform, Map:

```
<Sr> = <DF>.sum/max/mean/idxmax/all() # Or: <DF>.apply/agg(lambda <Sr>:
<el>)
<DF> = <DF>.rank/diff/cumsum/ffill/interpl() # Or:
<DF>.apply/agg/transform(lambda <Sr>: <Sr>)
<DF> = <DF>.fillna(<el>) # Or: <DF>.applymap(lambda <el>:
<el>)
```

- All operations operate on columns by default. Pass `'axis=1'` to process the rows instead.

```
>>> df = DataFrame([[1, 2], [3, 4]], index=['a', 'b'], columns=['x', 'y'])
   x  y
a  1  2
b  3  4
```

	'sum'	['sum']	{'x': 'sum'}
df.apply(...)		x y	
df.agg(...)	x 4 y 6	sum 4 6	x 4

	'rank'	['rank']	{'x': 'rank'}
df.apply(...)	x y	x y	x
df.agg(...)	a 1 1	rank rank	a 1
df.transform(...)	b 2 2	a 1 1 b 2 2	b 2

- Use `<DF>[col_key_1, col_key_2][row_key]` to get the fifth result's values.

## DataFrame — Plot, Encode, Decode:

```
import matplotlib.pyplot as plt
<DF>.plot.line/bar/hist/scatter([x=column_key, y=column_key/s]); plt.show()
```

```
<DF> = pd.read_json/html('<str/path/url>')
<DF> = pd.read_csv/pickle/excel('<path/url>')
<DF> = pd.read_sql('<table_name/query>', <connection>)
<DF> = pd.read_clipboard()
```

```
<dict> = <DF>.to_dict(['d/l/s/sp/r/i'])
<str> = <DF>.to_json/html/csv/markdown/latex([<path>])
<DF>.to_pickle/excel(<path>)
<DF>.to_sql('<table_name>', <connection>)
```

## GroupBy

Object that groups together rows of a dataframe based on the value of the passed column.

```
>>> df = DataFrame([[1, 2, 3], [4, 5, 6], [7, 8, 6]], index=list('abc'),
columns=list('xyz'))
>>> df.groupby('z').get_group(6)
   x  y
b  4  5
c  7  8
```

```
<GB> = <DF>.groupby(column_key/s)           # DF is split into groups based on
passed column.
<DF> = <GB>.apply(<func>)                     # Maps each group. Func can return
DF, Sr or el.
<GB> = <GB>[column_key]                     # A single column GB. All
operations return a Sr.
```

## GroupBy — Aggregate, Transform, Map:

```
<DF> = <GB>.sum/max/mean/idxmax/all()          # Or: <GB>.agg(lambda <Sr>: <el>)
<DF> = <GB>.rank/diff/cumsum/ffill()            # Or: <GB>.transform(lambda <Sr>:
<Sr>)
<DF> = <GB>.fillna(<el>)                        # Or: <GB>.transform(lambda <Sr>:
<Sr>)
```

```
>>> gb = df.groupby('z')
      x  y  z
3: a   1  2  3
6: b   4  5  6
   c   7  8  6
```

	'sum'			'rank'			['rank']		{ 'x': 'rank' }	
gb.agg(...)	x	y	z	x	y	z	x	y	x	
	z			a	1	1	rank	rank	a	1
	3	1	2	b	1	1	a	1	b	1
	6	11	13	c	2	2	b	1	c	2
							c	2		
gb.transform(...)	x	y	z	x	y	z				
	a	1	2	a	1	1				
	b	11	13	b	1	1				
	c	11	13	c	2	2				

## Rolling

Object for rolling window calculations.

```
<R_Sr/R_DF/R_GB> = <Sr/DF/GB>.rolling(window_size) # Also: `min_periods=None,
center=False`.
<R_Sr/R_DF>       = <R_DF/R_GB>[column_key/s]     # Or: <R>.column_key
<Sr/DF/DF>       = <R_Sr/R_DF/R_GB>.sum/max/mean() # Or:
<R>.apply/agg(<agg_func/str>)
```

## Plotly

```
# $ pip3 install plotly kaleido
from plotly.express import line
<Figure> = line(<DF>, x=<col_name>, y=<col_name>) # Or: line(x=<list>, y=
<list>)
<Figure>.update_layout(margin=dict(t=0, r=0, b=0, l=0)) # Or:
paper_bgcolor='rgba(0, 0, 0, 0)'
<Figure>.write_html/json/image('<path>')         # Also: <Figure>.show()
```

## Covid deaths by continent:

```
covid = pd.read_csv('https://covid.ourworldindata.org/data/owid-covid-data.csv',
                    usecols=['iso_code', 'date', 'total_deaths', 'population'])

continents =
pd.read_csv('https://gist.githubusercontent.com/stevewithington/20a69c0b6d2ff'
            '846ea5d35e5fc47f26c/raw/country-and-continent-codes-
            list-csv.csv',
            usecols=['Three_Letter_Country_Code',
                    'Continent_Name'])

df = pd.merge(covid, continents, left_on='iso_code',
              right_on='Three_Letter_Country_Code')
df = df.groupby(['Continent_Name', 'date']).sum().reset_index()
df['Total Deaths per Million'] = df.total_deaths * 1e6 / df.population
df = df[df.date > '2020-03-14']
df = df.rename({'date': 'Date', 'Continent_Name': 'Continent'}, axis='columns')
line(df, x='Date', y='Total Deaths per Million', color='Continent').show()
```

## Confirmed covid cases, Dow Jones, Gold, and Bitcoin price:

```
import pandas as pd
import plotly.graph_objects as go

def main():
    display_data(wrangle_data(*scrape_data()))

def scrape_data():
    def scrape_covid():
        url = 'https://covid.ourworldindata.org/data/owid-covid-data.csv'
        df = pd.read_csv(url, usecols=['location', 'date', 'total_cases'])
```

```

        return df[df.location == 'World'].set_index('date').total_cases
    def scrape_yahoo(slug):
        url = f'https://query1.finance.yahoo.com/v7/finance/download/{slug}' + \
            '?'
        period1=1579651200&period2=9999999999&interval=1d&events=history'
        df = pd.read_csv(url, usecols=['Date', 'Close'])
        return df.set_index('Date').Close
    out = scrape_covid(), scrape_yahoo('BTC-USD'), scrape_yahoo('GC=F'),

            side='right'),
            legend=dict(x=1.1),
            height=450
        ).show()

if __name__ == '__main__':
    main()

```

## PySimpleGUI

```

# $ pip3 install PySimpleGUI
import PySimpleGUI as sg
layout = [[sg.Text("What's your name?")], [sg.Input()], [sg.Button('Ok')]]
window = sg.Window('Window Title', layout)
event, values = window.read()
print(f'Hello {values[0]}!' if event == 'Ok' else '')

```

## Appendix

# Cython

Library that compiles Python code into C.

```
# $ pip3 install cython
import pyximport; pyximport.install()
import <cython_script>
<cython_script>.main()
```

## Definitions:

- All 'cdef' definitions are optional, but they contribute to the speed-up.
- Script needs to be saved with a 'pyx' extension.

```
cdef <ctype> <var_name> = <el>
cdef <ctype>[n_elements] <var_name> = [<el_1>, <el_2>, ...]
cdef <ctype/void> <func_name>(<ctype> <arg_name_1>, ...): ...
```

```
cdef class <class_name>:
    cdef public <ctype> <attr_name>
    def __init__(self, <ctype> <arg_name>):
        self.<attr_name> = <arg_name>
```

```
cdef enum <enum_name>: <member_name_1>, <member_name_2>, ...
```

## PyInstaller

```
$ pip3 install pyinstaller
$ pyinstaller script.py # Compiles into './dist/script'
directory.
$ pyinstaller script.py --onefile # Compiles into './dist/script'
console app.
$ pyinstaller script.py --windowed # Compiles into './dist/script'
windowed app.
$ pyinstaller script.py --add-data '<path>:.' # Adds file to the root of the
executable.
```

- File paths need to be updated to 'os.path.join(sys.\_MEIPASS, <path>)'.

## Basic Script Template

```
#!/usr/bin/env python3
#
# Usage: .py
#

from sys import argv, exit
from collections import defaultdict, namedtuple
from dataclasses import make_dataclass
from enum import Enum
import functools as ft, itertools as it, operator as op, re
```

```
def main():
    pass

###
## UTIL
#
